ABSTRACT

The Computer-Aided Prototyping System (CAPS) is an integrated collection of software tools that support the development of software systems utilizing the prototype paradigm. Central to CAPS is the Prototype System Description Language (PSDL). The PSDL Editor supplied in CAPS Release 1 provided a unique combination of a graphical interface for editing PSDL data flow diagrams and an attribute-grammar based text editor to enforce syntactically correct PSDL prototypes. Feedback from CAPS users highlighted on productivity impacts due to the dual user interface as well as the steep learning curve required to become proficient with the attribute-grammar based text editor.

This research initiates the development of the next generation of the CAPS PSDL Editor, focusing on the graph editor. Our approach provides a single graphical user interface with pull-down menus for editing both graphical and text information. Automatic syntax generation and validation as well as limited semantic validation is provided by a background syntax/semantics checker. The result of this research is a working graph editor meeting all the new requirements. When integrated with a the new syntax/semantics checker, CAPS Release 2 will have a PSDL Editor with enhanced capabilities and expected productivity improvements.

ACKNOWLEDGMENTS

Just as the development of the PSDL Editor has depended on many individuals, so has my education at the Naval Postgraduate School. Special thanks to my thesis advisors, Professors Man-Tak Shing and Valdis Berzins. But I would never have made it here without my mother and father. Nor would any of my stuff made it to Monterey if not for my sister, Karen, who packed my house. Lisa Fung and the Brown Haired Girl provided me with encouragement. And God opened every door. Thanks to all.

I would also like to thank the Linux Users Group at the Naval Postgraduate School. This entire thesis was written on a Linux platform using LaTeX. Figures used in this document were produced with XFig, XV, MetaPost, and daVinci. I would recommend that all Computer Science students become active in the Linux Users Group.

I. INTRODUCTION

A. BACKGROUND

The Computer-Aided Prototyping System (CAPS) [Ref. 1] is an integrated collection of software tools that support the development of software systems using the prototyping paradigm. The focus of CAPS is the development of hard real-time embedded software systems [Ref. 2]. Through the use of the prototyping paradigm, CAPS is especially well suited to support the development and validation of system requirements as well as feasibility studies [Ref. 3].

The software tools that comprise CAPS are organized into four major subsystems: Editors, Software Base, Execution Support, and Project Control (see Figure 1) [Ref. 4]. Underlying each of these subsystems is the Prototype System Description Language (PSDL) [Ref. 3].

Prototypes developed in CAPS are specified using PSDL PSDL is a highlevel language, rich in abstraction and with facilities for capturing the requirements

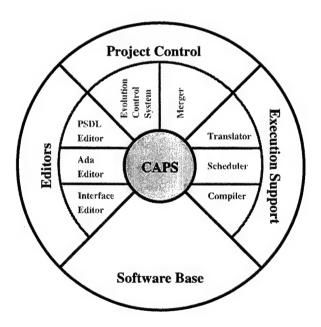

Figure 1. CAPS Subsystems, After [Ref. 4]

of real-time systems. In PSDL, a prototype is partially specified as an augmented data flow diagram. A representation of a PSDL prototype is provided in Figure 2. The augmented data flow diagram is depicted by the shaded box at the top of the figure.

A data flow diagram consists of a network of operators which communicate through data streams. The data flow diagram depicted in Figure 2 is composed of three operators (represented as circles) and two data streams (represented as the directed-lines connecting the circles within the shaded box). The data flow diagram is augmented with timing and control constraints. In Figure 2, each operator is assigned a Maximum Execution Time (MET), which can be found at the bottom-right of each operator. In this example, all MET values are in milliseconds (ms).

A data flow diagram is one element of a PSDL component. PSDL provides two kinds of components: abstract state machines and abstract data types. An augmented data flow diagram is a visual abstraction of the processing to be performed by an operator. Operators are introduced through PSDL components. An abstract state machine specifies a single operator. Multiple operators can be introduced as part of an abstract data type. The prototype itself is implemented as an operator defined by an abstract state machine. There are two parts to each component: a specification and an implementation. The specification defines the component's interface. The component's implementation can be realized by either decomposing the component into a more detailed data flow diagram or by a reference to a programming language implementation. Figure 2 depicts the top level data flow diagram of a robot prototype. In this example, each operator has been implemented with a reference to a programming language implementation, illustrated by the three boxes below the augmented data flow diagram. The current release of CAPS supports two programming language implementations. An operator can be implemented as an Ada package or as a TAE module, providing a graphical interface. [Ref. 5]

The Editor subsystem provides a collection of editors which are tailored to the

PSDL Data Flow Diagram

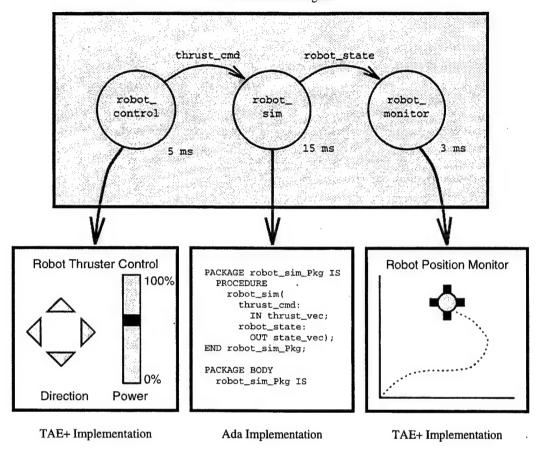

Figure 2. PSDL Data Flow Diagram and Implementation

ingredients of a CAPS prototype. The primary CAPS editor is the PSDL Editor. This editor is unique to CAPS and has been designed specifically for the development of PSDL prototypes. A graphical interface to support the data flow diagram as well as syntax generation and checking facilitate improved user efficiency in prototype development. Other editors are provided to edit the Ada packages and the TAE graphical interfaces which realize the prototype.

The Software Base subsystem provides CAPS with a repository of reusable prototype components. Facilities are provided to browse as well as query the component repository. Queries can be performed using the PSDL component specification.

[Ref. 6]

The Execution Support subsystem is one of the key features of CAPS which allows for rapid prototyping of real-time systems. The Execution Support subsystem provides for the automatic generation of "supervisory" code based on the PSDL specification of the prototype. The "supervisory" code provides scheduling of time critical and non-time critical operators, implements buffered communication paths (e.g., data streams) with applicable initial values, implements the control constraints specified in the prototype, and provides support for timers and exception handling. All of which is automatically implemented by CAPS.

The Project Control subsystem provides advanced project capabilities. The Evolution Control System facilitates prototype development in a team environment. The CAPS Merger provides an automated tool for change-merging of PSDL components. [Ref. 6]

CAPS has been an ongoing research area at the Naval Postgraduate School (NPS) for nearly ten years. During this time, CAPS has been used to develop a variety of student projects and theses, including an autopilot system, a cruise missile guidance system, and a Communications, Command and Control Information warfare (C3I) system. The current version of CAPS is Release 1. [Ref. 7]

B. CAPS RELEASE 1 PSDL EDITOR

The PSDL Editor provided in CAPS Release 1 facilitated the full specification of a prototype in PSDL (refer to Appendix A for the definition of the PSDL grammar). Departing from typical editors, the PSDL Editor provided facilities to view and edit the PSDL augmented data flow diagram in its most natural form, a graph (this functionality will be referred to as the "graph editor" in this document). However, the graph editor was limited in its capabilities to fully specify a prototype. The graph editor provided for the entry of the PSDL data flow diagram along with associated labels (i.e., operator and data stream names). In order to maintain a sim-

ple abstraction of the processing to be performed, the PSDL properties¹ displayed on the augmented data flow diagram were limited to those deemed most critical. For operators, the MET was supported. For data streams, the graph editor provided for the selection between a data stream and a state stream as well as for any stream latency. The remainder of the PSDL specification was supported through the use of a text editor.

Once again, the CAPS designers departed from typical editors with the inclusion of a syntax-directed editor to facilitate the required text editing. A syntax-directed editor is a language-based editor. With knowledge of a language's syntax, a syntax-directed editor is capable of detecting and locating syntax errors. For CAPS, this means that PSDL syntax errors can be corrected in the editor rather than waiting for them to be detected by the Execution Support subsystem. In addition, a syntax-directed editor can provide the user with templates for structures within the language. The syntax-directed editor provided in CAPS Release 1 was implemented using the Synthesizer Generator, a commercial product developed by Thomas Reps and Tim Teitelbaum [Ref. 8].

Provided with a definition of a language's abstract syntax, context-sensitive relationships, display format, concrete input syntax, and transformation rules, the Synthesizer Generator produces a language-based editor. Fundamental to the operation of the Synthesizer Generator is the use of an attribute grammar. An attribute grammar is obtained by the addition of attributes to the nonterminal symbols of a context-free grammar along with a set of attribute equations. As an object is edited with a syntax-directed editor (created by the Synthesizer Generator), the object is represented internally by a derivation tree, which is based on the attribute grammar. It is the derivation tree which is traversed and modified through editing operations. [Ref. 8]

¹PSDL properties will be discussed in Chapter II. For the present, the MET and the Latency are timing requirements of the prototype. A state stream is a special case of a data stream which provides the prototype with memory.

In the CAPS Release 1 PSDL Editor, the graph editor and the syntax-directed editor were merged together to provide an integrated tool to facilitate the development of prototypes. The PSDL Editor was implemented by executing the syntax-directed editor and the graph editor in separate processes. The syntax-directed editor was the parent process. Two copies of the graph editor were executed, each in its own process. Upon startup of the syntax-directed editor, the first copy of the graph editor was created as a graph viewer. As the PSDL prototype was traversed in the syntax-directed editor, the graph viewer displayed the applicable data flow diagram. In order to edit the data flow diagram, a second copy of the graph editor was created as a graph editor.

The implementation of the CAPS Release 1 PSDL Editor resulted in the creation of an artificial boundary between the data flow diagram and the associated PSDL properties. This artificial boundary resulted in a two step process of prototype development for the typical CAPS user. In this process, the user would create the data flow diagram of the prototype using the graph editor (reference Figure 3²). When the data flow diagram was reasonably complete, the user would return to the syntax-directed editor (reference Figure 4), where the associated properties would be entered.

The separation between the syntax-directed editor and the graph editor fostered a single mind-set of operation in which all of the data flow diagram was entered prior to the use of the syntax-directed editor to enter the associated properties. State streams presented a large potential for error. If a user specified a state stream in the data flow diagram through the graph editor, the state stream was not implemented until the user again specified the state stream in the syntax-directed editor.

The templates available in the syntax-directed editor provided assistance to the user in developing a syntactically correct prototype. At each stage of a prototype's development, the syntax-directed editor was capable of prompting the user for the

²This prototype is taken from the avionics_example found in Appendix B.

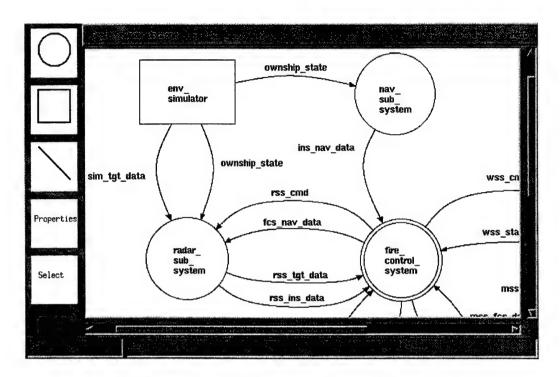

Figure 3. CAPS Release 1 Graph Editor

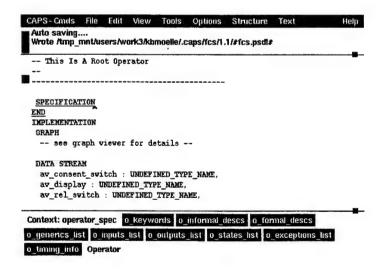

Figure 4. CAPS Release 1 Syntax-Directed Editor

legal alternatives within the PSDL grammar (refer to the bottom of Figure 4). In addition, the knowledge of templates enabled the syntax-directed editor to perform operations on entire structures, made available to the user from the Structure menu (refer to the top of Figure 4).

However, due to differences between the attribute grammar programmed into the syntax-directed editor and the PSDL grammar definition (refer to Appendix A), the traversal of the derivation tree maintained by the syntax-directed editor was not always intuitive to the user. In some cases, additional nodes were inserted into the derivation tree which confused the user. In order to become proficient with the PSDL Editor, the user was required to become familiar with the unique features of the attribute grammar.

A typical example is the editing of a type_declaration within a data stream structure. Figure 5 depicts a graphical representation of the type_declaration structure from the PSDL grammar definition (starting with line 25 of Appendix A). Figure 6 depicts how the same structure would be represented in the derivation tree of the syntax-directed editor, based on the attribute grammar. The derivation tree provided additional nodes to represent the set of types which were allowed INTEGER. REAL, BOOLEAN, and User_Defined. However, the definition of the attribute grammar was not intuitive to the typical CAPS user. Figure 7 depicts four snapshots of the syntax-directed editor in an example where the user wishes to modify the type used for the data stream av_consent_switch. Initially, the data stream is of type switch_position, a User_Defined type. The required type for the data stream is BOOLEAN. The user selects the type name, depicted by the underlined switch_position in the first snapshot. The user deletes this entry and expects to be presented with the decl_type_name options. However, syntax-directed editor is still located at the id node below DTypeUserDefined within the derivation tree (refer to the second snapshot). The user is required to ascend to the parent (i.e., decl_type_name) from the Structure menu and cut off the existing branch of the

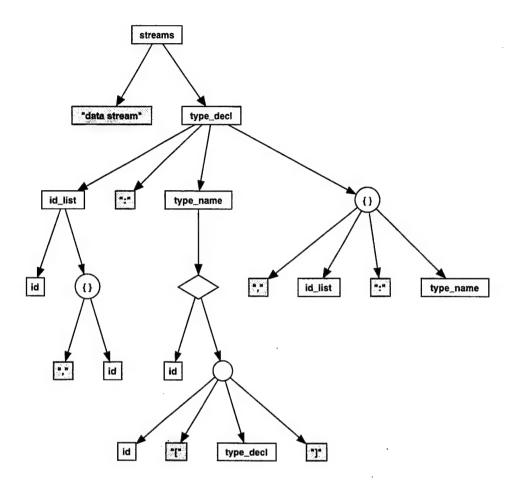

Figure 5. PSDL Type Declaration

derivation tree from the Edit menu (depicted in the third snapshot). The syntax-directed editor is now positioned within the derivation tree to prompt for the BOOLEAN option, which is selected and depicted in the fourth snapshot.

Additionally, the syntax-directed editor's attribute grammar stipulates an order in which PSDL structures can be arranged. In some cases, this order is defined in the PSDL grammar. In other cases, it is solely defined by the syntax-directed editor. Regardless of the PSDL grammar, the syntax-directed editor requires a specific ordering of PSDL structures. The syntax-directed editor provides the user assistance

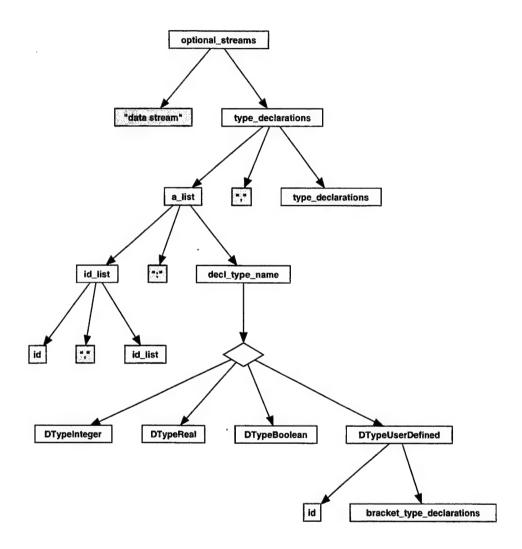

Figure 6. Derivation Tree Type Declaration

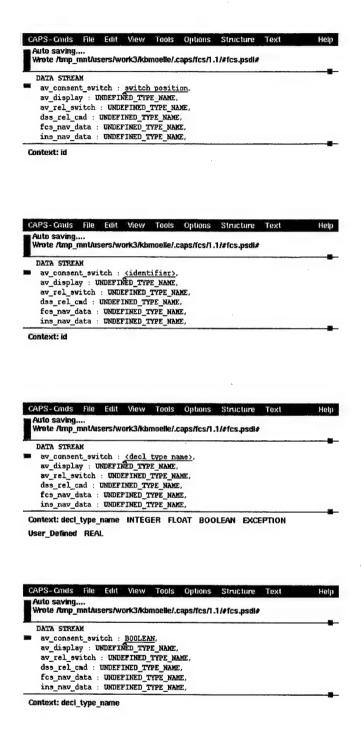

Figure 7. Syntax-Directed Editor: Derivation Tree Traversal

by prompting for all valid constructs at the cursor location. However, the user is required to either memorize the order stipulated by the attribute grammar or to search through the prototype in order to identify the location for the desired construct.

C. RESEARCH GOAL

While the PSDL Editor provided advanced features for specifying the requirements of a prototype in PSDL, it also introduced artificial boundaries and linear constraints that impacted a users productivity. The goal of this research is to develop the next generation of the PSDL Editor in an attempt to overcome these impediments.

As this research was envisioned, the development of the next generation of the PSDL Editor was divided between the graph editor and a background checker driver, written in Ada. This research was centered about the graph editor. This project was implemented as an evolutionary task. The CAPS Release 1 graph editor was used as the baseline from which this research was initiated. Additional work on the graph editor was accomplished partly through the class project for NPS CS4520 (AY96Q4).

II. PROTOTYPE SYSTEM DESCRIPTION LANGUAGE (PSDL)

The primary reference for the Prototype System Description Language is the paper "A Prototyping Language for Real-Time Software" by Luqi, Berzins, and Yeh [Ref. 3]; which describes the semantics of PSDL. Refinements to the PSDL semantics are outlined in Professor Luqi's class notes from the Naval Postgraduate School course CS4920: Computer Aided Prototyping Systems (AY96Q3) [Ref. 9]. These two sources, along with the PSDL syntax provided as Appendix A, define PSDL.

This chapter provides an introduction to PSDL as background information for a discussion of the PSDL Editor. Here PSDL is described within the context of a CAPS tool set implementation. This serves two purposes. First, a background in PSDL is necessary in order to understand the required operation of the PSDL Editor. CAPS provides a language-sensitive editor. The PSDL Editor is solely dedicated to CAPS, incorporating many language dependent features designed to simplify the specification of a PSDL prototype. Second, this introduction serves to inform the CAPS user of limitations imposed by a CAPS implementation which deviate from the PSDL semantics.

CAPS provides a set of integrated tools (reference Figure 1) designed to facilitate the development of executable prototypes using PSDL. Limitations within the tool set have resulted in a CAPS implementation that does not fully comply with the PSDL semantics. With each new release of CAPS, an attempt is made to remove these limitations. This research effort comes between CAPS implementations. Currently, CAPS is at Release 1. Release 2 is planned, but not yet fully defined for all CAPS subsystems. Release 2 does contain PSDL syntax changes. These changes are reflected in this introduction as well as in the next release of the PSDL Editor. However, any changes which may be incorporated into the Execution Support subsystem tools (excluding those changes needed to support the new PSDL syntax) are unde-

fined at this time, and hence are not addressed here. Thus, the PSDL configuration which is addressed here is the CAPS Release 1 implementation with the addition of the CAPS Release 2 updated syntax. As a result of the syntax changes which will make up CAPS Release 2, prototypes developed with this PSDL Editor will not be compatible with CAPS Release 1.

Since CAPS users are presented with an implementation which does not fully support the PSDL semantics, users could potentially design a prototype which utilizes a limitation. Limitations with an implementation require special consideration by the prototype developer and may require the designer to over-constrain the prototype in order to work around a limitation. For example, within the PSDL semantics, stream names are local. However, the CAPS Release 1 implementation operates as if stream names are global. In order to maintain the semantics of PSDL, a prototype designer must over-constrain the prototype by forcing unique stream names in order to maintain local streams.

Thus, concessions must be made in the prototype design to make up for limitations in the support provided by the tools. The concessions provided here are in full compliance with the PSDL syntax. They simply over-constrain the design in order to work around a limitation. Prototypes which adhere to these concessions should be compliant with future releases of CAPS. Prototypes which do not adhere to the correct semantics of PSDL will most likely "break" in future releases.

A. PSDL PROTOTYPE

Figure 8 depicts the partial taxonomy of a PSDL prototype. A PSDL prototype consists of a set of components. PSDL provides two kinds of components: abstract state machines and abstract data types. An operator is an instance of an abstract state machine and can be introduced into the prototype by either an abstract state machine component or an operator of an abstract data type component. In PSDL, the operator is the basic computational entity [Ref. 10].

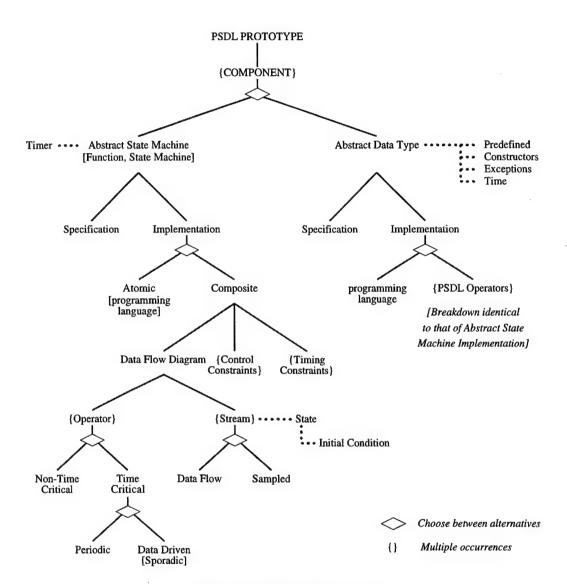

Figure 8. PSDL Taxonomy

A prototype is decomposed into a network of operators which communicate through data streams. Data streams carry objects of a fixed data type. Data stream objects can be either predefined data types or types defined by abstract data type components.

The PSDL syntax provides for the description of this network as a data flow diagram in which the vertices represent operators and the edges represent data streams. By itself, the data flow diagram is not sufficient to support the definition of a real-time system. PSDL augments the data flow diagram with control and timing constraints. The augmented data flow diagram together with a set of precedence rules provides sufficient information for the CAPS Execution Support subsystem to automatically generate the "supervisory" code used to control the execution and communications of operators.

While the operator is the PSDL computational entity, the PSDL syntax does not provide for the complete implementation of all operators. A general purpose programming language is required to implement some operators³. Currently, CAPS supports the programming languages Ada and TAE to implement operators. CAPS generates Ada code for "supervisory" control.

The "supervisory" code generated by the CAPS Execution Support subsystem controls the execution of PSDL operators. As can be seen from Figure 8, PSDL contains both time critical and non-time critical operators. Time critical operators are controlled by a static schedule. Non-time critical operators are controlled by a dynamic schedule. The static schedule is executed as a high priority Ada task. The dynamic schedule is executed as a lower priority Ada task that runs whenever the static schedule idles. [Ref. 9]

³Operators which are implemented using a general purpose programming language are called atomic operators.

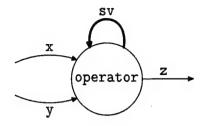

Figure 9. State Machine example

1. Component Structure

Every PSDL component is made up of two parts: a specification and an implementation. The specification defines the component's interface and provides for the documentation of behavior and requirements tracing. The implementation can be performed using a PSDL supported programming language (for atomic operators) or further defined in PSDL (for composite operators).

2. Abstract State Machines

A PSDL operator is a state machine. A state machine contains a finite number of inputs, outputs, and state variables; each of which are represented as a data stream. Figure 9 provides an example of a state machine with two input streams (x and y), one output stream (z), and one state variable⁴ (sv). A function is a state machine with no state variables.

When the state machine is executed, it reads one data object from each of the input streams. The output values of the state machine depend solely upon the current values of the input objects that were read and the current value of the state variables. At most, one data object is written to each output stream. [Ref. 3]

An operator that is implemented using a PSDL supported programming lan-

⁴In this example, state variables are depicted with bold lines. This is the convention used by the graph editor.

guage is referred to as atomic. In this case, the operator's implementation specifies the programming language as well as the module name used to implement the operator. Operators that are not atomic are composite. A composite operator is itself decomposed into a network of operators; communicating through data streams. This establishes a parent-child relationship between operators. The composite operator being the parent and the operators contained in the decomposed network being the children.

Composite operators provide for a hierarchical decomposition of a prototype. At the top most level, the prototype consists of a single operator, referred to as the root operator⁵. Children of the root operator can either be implemented as atomic operators or as composite operators. At the lowest level, all operators are implemented as atomic operators.

PSDL provides timers as predefined abstract state machines. A timer behaves similar to a stopwatch. A timer is modeled as an elapsed time value and a run switch. As long as the run switch is on, the elapsed time value is incremented. Timers have four operations: start, stop, reset, and read. Start turns on the run switch. Stop turns off the run switch. Reset turns off the run switch and sets the elapsed time value to zero. Read returns the current value of the elapsed time. [Ref. 3]

Timers are declared in the implementation section of a composite operator. Timers differ from operators in that they do not appear in the data flow diagram. Timer values (i.e, the result of a read operator) are accessed by referring to the timer by name within the control constraints of an operator. PSDL semantics provide for the insertion of a timer value into a data stream [Ref. 3]. Currently, this feature is not supported in the CAPS tools. The prototype designer should limit the use of timers to operator constraints.

⁵The PSDL Editor only supports the root operator being implemented as a composite operator.

3. Abstract Data Types

The abstract data type component introduces a new type name for a user defined type. An abstract data type defines a set of values and a set of operations on that value set [Ref. 11]. User defined data types are provided in addition to the set of predefined data types: boolean, character, string, integer, real, and exception. All PSDL abstract data types are immutable. An immutable type has a fixed set of values and the properties of an instance of a type cannot be changed [Ref. 11]. PSDL has no mutable types or global variables⁶ in order to prevent coupling problems between operators [Ref. 3].

The set of operations defined by an abstract data type component are implemented as PSDL operators. Similar to operators defined by an abstract state machine component, an operator defined in an abstract data type component can be implemented either in a PSDL supported programming language or as a PSDL augmented data flow diagram. Since an immutable type has no memory (i.e., no state variables) [Ref. 11], it is a good design principle to limit abstract data type operators to functions and avoid state machines and timers.

Data streams carry objects of an abstract data type, the data stream type being assigned in a PSDL type declaration construct. Abstract data type operators can appear within a data flow diagram as an operator by providing the type name and the operator name separated by a '.' (e.g., stack.push where stack is the type name and push is the operator name).

Unusual behavior of an operator can be flagged through the use of an exception. PSDL facilitates this through the use of the built-in abstract data type of exception. Exceptions are identified by name. PSDL provides for the raising of an exception of a given name, detecting the presence of an exception with a given name,

⁶The PSDL semantics specify that all streams are local. However, as currently implemented in CAPS Release 1, streams are global, based on the stream name. Thus, to be consistent with PSDL semantics, streams that are not local should have unique names. This is a concession made in the design of the prototype to work around a limitation in the CAPS tool set implementation.

and determining if no exception was raised (i.e., normal).

The PSDL syntax provides for a time literal (reference production rule 36 of Appendix A) which consists of an integer and an associated time unit (i.e., microseconds, milliseconds, seconds, minutes, or hours). CAPS Release 1 does not support any time resolution less than one millisecond. Thus, the CAPS Execution Support subsystem converts all time literals to a natural number of milliseconds. Any time literal less than a millisecond is converted to one millisecond. The PSDL does not provide a predefined abstract data type which can be used to support time literals.

B. DATA FLOW DIAGRAM

At the top level, a prototype consists of an operator, whose implementation is provided by an augmented data flow diagram. After the initial operator (i.e., the prototype level), the designer may choose to implement the behavior of an operator with a network of simpler operators or with an atomic operator. This process of decomposing complex operators into simpler composite operators is continued until all remaining operators are atomic. The resulting structure is a hierarchical tree, in which the root is the prototype operator, all internal nodes are implemented as composite operators, and all leaf nodes are implemented as atomic operators.

An augmented data flow diagram consists of a data flow diagram depicting a network of operators (communicating through data streams) as well as control and timing constraints on the network. A sample prototype is depicted in Figure 10, in which two data flow diagrams are included. The root operator is implemented as a composite operator, and hence has an associated data flow diagram. The operator b is also a composite operator and contains an associated data flow diagram.

A data flow diagram can accept inputs from an external producer and produce outputs which are used by an external consumer. The inputs and outputs of a composite operator are declared in the composite operator's specification section. These inputs and outputs correspond to the inputs and outputs depicted in the parent data

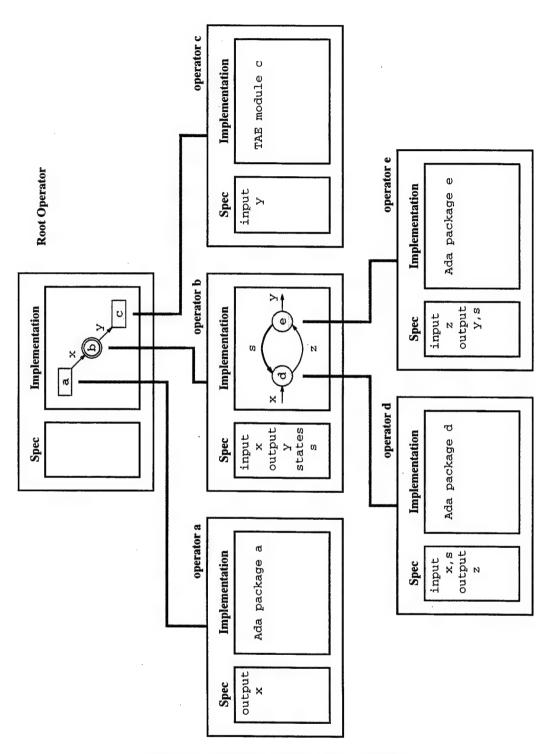

Figure 10. Sample PSDL Decomposition

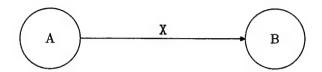

Figure 11. Operator Precedence Relationship

flow diagram. This can be seen in Figure 10. Within the operator b component, the specification declares x to be an input and y to be an output. These inputs and outputs correspond to the streams into and out of the subject operator (i.e., b) depicted in the parent data flow diagram (i.e., the root operator). The root operator corresponds to a closed system, in which there are no external inputs or outputs.

While the PSDL syntax supports a textual description of the augmented data flow diagram, the PSDL Editor provides a graphical interface to the user for creating, maintaining and browsing the data flow diagram. Within the graphical interface, an operator is represented as a bubble and a data stream is represented as a directed line segment from the producer operator to the consumer operator.

A precedence relationship establishes a partial ordering of the execution schedule based on the data stream paths between operators. Figure 11 depicts two operators, A and B, which share a data stream, X. The execution of B requires the availability of data from X. Hence, operator A must be executed prior to the execution of operator B.

Figure 12 depicts the same state machine with a feedback loop added, data stream FB. In this situation, each operator depends on the output of the other operator. CAPS requires that every cycle within a data flow diagram be broken with a state stream. That is, one of the data streams on the cycle must be designated a state stream and provided with an initial value. The initial value of the state stream breaks the circular precedence relationship that would otherwise be impossible to schedule. In order to obtain a valid PSDL prototype, the designer must ensure that the data streams (excluding state streams) of every data flow diagram form a directed acyclic

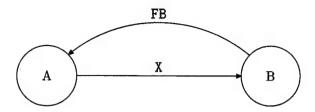

Figure 12. Cyclic Precedence Relationship

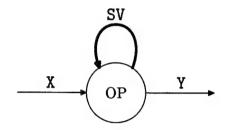

Figure 13. Data Flow Diagram Loop

graph (DAG). Each cycle which is found in the data streams of a data flow diagram must be broken, either by the removal of a data stream or by designating one of the data streams to be a state stream. This rule applies to simple loops as depicted in Figure 13.

1. Operators

In support of real-time prototypes, PSDL provides both time critical and non-time critical operators (reference the taxonomy of an operator depicted in Figure 8). Execution of time critical operators can be triggered either periodically or sporadically (i.e., data driven).

In order for the CAPS Execution Support subsystem to obtain a schedule which executes each operator consistently with the timing constraints of the augmented data flow diagram, a bound must be placed on the execution time of the operators. This bound is referred to as the **maximum execution time** (MET). An operator is time critical if and only if it has been assigned an MET. Otherwise, the

operator is non-time critical. [Ref. 3]

A time critical operator is triggered periodically if it contains a **period** (P) timing constraint. Otherwise, the operator is triggered sporadically, based on the arrival of data (i.e., data driven), and must contain a data trigger control constraint.

Since a PSDL prototype represents a closed system, often it is necessary to include operators which are not considered to be part of the prototype to create the closed system. PSDL facilitates the inclusion of these external systems as terminators. Terminators are operators with an assigned MET of zero⁷, and thus the time required to execute the terminator is not counted against the prototype execution time. The CAPS maintains a simulated real-time clock. During the execution of a terminator, the simulated real-time clock is turned off. Terminators are represented in the PSDL Editor by a rectangular bubble within the data flow diagram. Operators with a non-zero MET (including those operators with an undefined MET) are represented in the PSDL Editor by a circular bubble.

2. Streams

Streams are used to communicate data objects of a fixed data type from a set of one or more producer operators to a set of one or more consumer operators [Ref. 9]⁸. While the PSDL syntax and the PSDL Editor represent a stream as a link from one producer to one consumer, multiple producers and multiple consumers are supported by matching stream names (i.e., identifiers) within the stream scope.

PSDL provides two types of data streams: data flow streams and sampled streams. A data flow stream guarantees that no data object is lost or replicated. The data flow stream behaves like a first-in-first-out (FIFO) queue with a length of one for each consumer. A sampled stream behaves like a single memory cell which contains one data object for each consumer. The most recent data value is obtained each time

⁷Since all terminators have an MET of zero, they are considered time critical and are placed on the static schedule.

⁸This implementation is a change from that presented in [Ref. 3].

the stream is read. Thus, data objects may be lost if associated with a fast producer or replicated if associated with a slow producer. The type of data stream used is determined by the consuming operator's trigger control constraint. If the consuming operator contains a **triggered by all** control constraint for a set of streams, those streams are data flow streams. Otherwise, the stream is a sampled stream.

The FIFO queue length of one for a data flow stream restricts the relative execution rates between the producer and consumer operators. In order to guarantee that no data object is lost or replicated, the output rate of the producer must not exceed the execution rate of the consumer for all data flow streams. No such restriction is placed on a sampled stream.

3. State Streams

State streams provide a state machine with memory. State streams are also used to schedule data flow diagrams that would otherwise be impossible to schedule due to circular precedence constraints. A state stream is declared in the specification section of the component in which the state stream first appears in the data flow diagram. In Figure 10, the state stream s first appears in the data flow diagram of operator b. The state stream declaration appears in the specification of operator b as well. Within the components of operators e and d, the producer and consumer of s respectively, s only appears within the specification's output and input declarations.

A state stream differs from a data stream in that a state stream must include an initial value. It is the initial value of a state stream which makes it possible for a state stream to break a circular precedence constraint. A state stream is also required when connecting time critical and non-time critical operators [Ref. 9].

Note that, under CAPS Release 1, all state streams are implemented as sampled streams regardless of the trigger constraint. Data flow state streams are not provided.

Table I. PSDL Constraints

	Operator		
Constraint	Non-Time Critical	Tim	e Critical
		Periodic	Sporadic
MET	Undefined	Required	Required
Period		Required	
Finish Within		default: Period	
MRT			$\operatorname{Required}^a$
MCP			default: MRT-MET
Data Trigger	Optional	Optional	Required
Conditional Exec	Optional	Optional	Optional
Output Guard	Optional	Optional	Optional
Exceptions	Optional	Optional	Optional
Timers	Optional	Optional	Optional

Constraint	Operator		Constraint	Stream	
	Terminator	Operator		Data Flow	Sampled
MET	0	Otherwise	Data Trigger	by all^b	Otherwise

^aIf MCP is set instead, MRT defaults to MCP+MET.

4. Constraints

Constraints augment the data flow diagram in order to control the execution of operators, generation of output, processing of exceptions, and timers. Constraints also determine the implementation of data streams. Table I lists the constraints required to obtain a specified functionality of operators and streams as well as those constraints which are optional.

Execution guards provide for the conditional execution of an operator. Execution guards are provided by the constructs:

operator
$$\langle op_id \rangle$$
 [triggered by all $\langle id_list \rangle$] [if $\langle expression \rangle$] operator $\langle op_id \rangle$ [triggered by some $\langle id_list \rangle$] [if $\langle expression \rangle$]

Only one of the above constructs is permitted for each operator of a data flow diagram. Each construct has two conditions, a data trigger condition and an if condition. The

^bUnder CAPS Release 1, all state streams are implemented as Sampled Streams.

two conditions can be used independently or together to provide an execution guard on the operator.

The data trigger condition **triggered by all** is satisfied only if all of the streams listed in the $\langle id list \rangle$ have new data objects (i.e., has been written to since the last read operation). The data trigger condition **triggered by some** is satisfied if at least one of the streams listed in the $\langle id list \rangle$ has a new data object. A data trigger condition is required for a sporadic operator. It is an optional execution guard for periodic and non-time critical operators. As can be seen in Table I, the **triggered** by all condition is also used to designate a stream as a data flow stream for the consuming operator.

The second condition within the execution guard is the if condition. Identifiers of the conditional $\langle expression \rangle$ are limited to those of input streams as well as those of visible timers and exceptions.

Output guards provide for the conditional transmission of an operator's output stream. The operator's result is not transmitted over the stream unless the output guard expression is satisfied. One output guard is permitted for each of the operator's output streams. Identifiers of the output guard expression are limited to those of the operator's input and output streams as well as those of visible timers and exceptions.

Exception guards provide for the conditional raising of an exception. Multiple exception guards are permitted, one for each exception to be raised. The resulting exception is transmitted on all output streams of type exception leaving the operator, subject to any output guard constraints defined for those streams. Identifiers of the exception guard conditional expression are limited to those of the operator's input and output streams as well as those of visible timers and exceptions. If the exception guard conditional expression is missing, it is assumed to be true.

Timer control constraints provide for the conditional control of a timer. Conditional control is provided to start, stop, and reset a timer. Identifiers of the timer control conditional expression are limited to those of the operator's input and out-

Table II. PSDL Timing Constraints; From [Ref. 6]

Periodic Operator	Sporadic Operator
Maximum Execution Time (MET)	Maximum Execution Time (MET)
Period (P)	Minimum Calling Period (MCP)
Finish Within (FW)	Maximum Response Time (MRT)

put streams as well as those of visible timers and exceptions. If the timer control conditional expression is missing, it is assumed to be true.

There are five⁹ timing constraint parameters used for a PSDL operator. These parameters are listed in Table II, under the class of time critical operators where they are used, and are defined as follows [Ref. 6]:

- Maximum Execution Time (MET) An upper bound on the execution time from start to finish of an operator.
- **Period** (P) The elapsed time between two successive triggerings of a periodic operator at the earliest possible moment.
- **Finish Within (FW)** An upper bound on the elapsed time that may pass between the earliest time that a periodic operator can be triggered and the latest time the operator must produce all output stream values.
- Minimum Calling Period (MCP) A lower bound on the amount of time that may pass between successive triggerings of a sporadic operator.
- Maximum Response Time (MRT) An upper bound on the amount of time that may elapse from the arrival of data which triggers an operator to the time that all output streams have been produced.

The absence of a MET constraint is used to indicate that the operator is non-time critical. Otherwise, the operator is time critical. Only time critical operators are allowed to have timing constraints [Ref. 9]. Only the MET is displayed by the PSDL Editor on the data flow diagram.

⁹MET appears twice in Table II, under both Periodic and Sporadic operators.

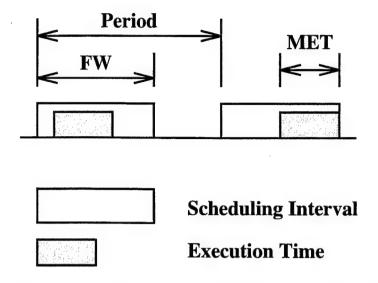

Figure 14. Periodic Timing Constraints; From [Ref. 9]

Periodic operators are scheduled at nearly regular time intervals. Figure 14 depicts the relationship between the timing constraints for a periodic operator. The MET and Period (P) must be assigned for a periodic operator. If a FW constraint is not specified, it is defaulted to P.

Jitter is an upper bound on the time that may elapse between two successive executions of a periodic operator. The worst case of jitter is obtained with the default value of the FW constraint (i.e., FW = P). In such a case, the jitter is given by twice the difference of the P and the MET. Jitter can be reduced to zero by setting the FW constraint equal to the MET.

Sporadic operators are triggered by the arrival of data. Figure 15 depicts the relationship between the timing constraints for a sporadic operator. The MET must be assigned along with either the MCP or the MRT or both.

Limits are placed on the values of MCP and MRT in the absence of a pipelined execution implementation. The MCP must be greater than or equal to the MET. The MRT must be greater than or equal to twice the MET. If the MRT constraint is specified and the MCP constraint is left unspecified, then the MCP defaults to the

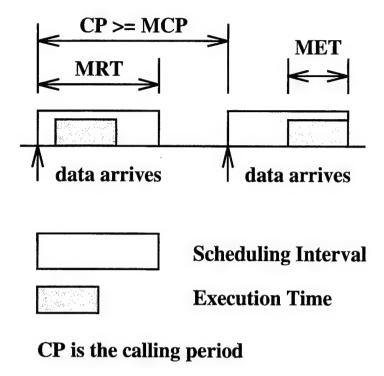

Figure 15. Sporadic Timing Constraints; From [Ref. 9]

difference between the MRT and the MET. If the MCP constraint is specified and not the MRT constraint, then the MRT defaults to the sum of the MCP and the MET.

One additional timing constraint is provided for streams. Latency is the lower bound on the elapsed time from when data is written to a stream by the producer until the time that the data can be read from the stream by the consumer. Latency is also displayed by the PSDL Editor in the data flow diagram.

C. HIERARCHICAL NETWORK

A PSDL prototype is built of PSDL operators, implemented as either data flow diagrams or with a PSDL supported programming language, in a hierarchical manner. The root operator is at the top of the hierarchy, which is always implemented as a data flow diagram. Each of the operators referenced in the data flow diagram is also specified as a PSDL component (either as an abstract state machine or as an

operator of an abstract data type).

The specification of each operator establishes the interface to the operator while the details are hidden in the implementation. For a given operator, the inputs and outputs declared in the specification correlate to the input and output streams of the corresponding operator of the parent's data flow diagram. States depicted in the data flow diagram found in an operator's implementation are also declared in that operator's specification. Exceptions processed in an operator's implementation are also declared in that operator's specification. Timers processed in an operator's implementation are declared in that operator's implementation. The declaration of input and output streams, state streams, and exceptions is provided for with the automatic PSDL code generation of the PSDL Editor. However, the PSDL Editor has no provisions for the automatic generation of the timer declaration. It is the responsibility of the user to properly declare all timers.

The use of a hierarchical structure comes with additional semantic requirements.

1. Root Operator

A PSDL prototype contains a single root operator. Any operator that is not in a hierarchical decomposition of the root operator is considered to be a multiple root operator and represents an error. Use of the PSDL Editor ensures that a multiple root operator error can not occur. A single root operator is provided by the PSDL Editor upon entry. All subsequent operators are introduced as decompositional operators within a hierarchy. Within the PSDL Editor, if a composite operator is deleted, the child operators will be deleted.

CAPS follows the convention that the name¹⁰ of the root operator is the same as that of the file name that contains the prototype. The extension ".psdl" is added

¹⁰In order for CAPS to provide for duplicate operator names in different scopes, the PSDL Editor appends an operator identification number to the operator name. This identification number is not included in the PSDL prototype file name.

to the file name.

While not limited in the PSDL syntax, the PSDL Editor limits the root operator to one which corresponds to a closed system. There are no inputs to, or outputs from, the root operator. If inputs and/or outputs are required, the scope of the prototype should be expanded so that the required inputs and/or outputs are contained within the prototype¹¹. The only $\langle attributes \rangle$ (reference production rule 8 in Appendix A) permitted within the specification of the root operator are **generic**, states, and exceptions.

In addition, the PSDL Editor limits the root operator of the prototype to a PSDL implementation. No provisions are made in the PSDL Editor for a root operator implemented in a programming language.

2. Stream Consistency

Within the hierarchical structure of PSDL, a composite operator is implemented as a data flow diagram of a PSDL component at a lower level. All inputs to the composite operator must be utilized as an external input to at least one of the operators in the decomposed data flow diagram. Likewise, all outputs of the composite operator must be utilized as an external output from at least one of the operators in the decomposed data flow diagram. A similar set of rules require that all external inputs to a decomposed data flow diagram must be inputs to the composite operator and all external outputs to a decomposed data flow diagram must be outputs from the composite operator. [Ref. 3]

External streams in a decomposed data flow diagram inherit the stream's data object type of the the composite operator. In addition, which type of stream (i.e., data flow stream or sample stream) is derived from the trigger constraint of the

¹¹User provided inputs as well as output displays to the user are typically handled by an operator (or terminator) contained within the prototype. Such an input/output operator may be implemented in TAE. While user input and/or output may be considered external, the use of an operator (terminator) to capture the requirements and specification of the input and/or output is considered to "close" the prototype system.

consuming operator. For a composite operator, as explained above, an input to a composite operator must also be an input to at least one operator in the decomposed data flow diagram. The trigger constraints of both the composite operator and those of the applicable decomposed operators are used in the derivation of the type. [Ref. 3]

3. Timing

The MET and the MRT of a composite operator must be consistent with the implementation of the operator as a data flow diagram. The MET and the MRT of the implementing data flow diagram must be no larger than that of the composite operator. The Period and the MCP of a composite operator are inherited be the the operators of the implementing data flow diagram.

4. Visibility

The CAPS semantics requires that operator names within a composite operator are to be local to the component. In order to accomplish this, the PSDL Editor supports integer suffixes which are attached to the operator name (reference memo provided in Appendix C). This feature will not be available until CAPS Release 2.

The CAPS semantics provides for all streams to be local. Streams with an identical name out of a common operator are local. Streams with identical names, but out of different operators are not local. However, as implemented in CAPS Release 1, streams are global. That is, any two streams with a common name are visible. In order to maintain the PSDL semantics, all streams that are not desired to be local should have unique names. This is a concession made in the prototype design to workaround an implementation limitation of CAPS Release 1.

When an exception is raised by an operator, the exception is transmitted on all data streams of type exception, regardless of the exception stream label, leaving the operator, subject to the stream output guard. The exception is transmitted only over local exception streams. Thus the exception is not transmitted over exception streams which are outputs of another operator. At least one exception output stream should be provided for each operator which is capable of generating an exception.

[Ref. 9]

A timer is visible within the component in which it is declared. If the component's data flow diagram contains a composite operator, then the timer is visible within the decomposed components.

D. LEXICAL ELEMENTS

Each PSDL component is composed of a sequence of lexical elements. Lexical elements are in turn composed of characters. A lexical element is either an integer literal, a real literal, a string literal, text, an identifier (including keywords), or a delimiter¹².

When a prototype is maintained by the PSDL Editor, the editor will ensure that the prototype is syntactically correct. User input provided through the PSDL Editor's graphical interface are validated as required and are automatically translated into a syntactically correct PSDL prototype. Thus many of the rules presented in this section do not impact the prototype developer since they are maintained by the PSDL Editor. If a developer chooses to maintain a prototype using any other system, it is the responsibility of the developer to adhere to the syntax of PSDL. Very little assistance in the form of error messages is provided to the developer who introduces syntactical errors into a prototype. In most cases, the PSDL Editor will not be able to recover from these syntax errors.

1. Character Set

The PSDL character set is composed of the 95 printable ASCII characters from ASCII ''_' (space) through ASCII '^' (tilde) plus the line feed (ASCII character 10) and horizontal tab (ASCII character 9) characters.

¹²The time literal mentioned earlier is not truly a literal. Rather, it is a grammatical rule which combines an integer literal with a keyword representing the time units.

Right brace, '}', is a special character in that it is included in the PSDL syntax, however, it is not allowed to appear anywhere except the closing of a **description** or an **axioms** structure (reference production rule 45 of Appendix A for the definition of a character and production rules 15 and 16 for the use of '}'). The format effectors vertical tab, carriage return, and form feed can not appear anywhere other than the $\langle text \rangle$ field of the **description** or the **axioms** structures¹³.

2. Integer Literals

An integer literal (reference production rule 43 of Appendix A) is an unsigned number. All integer literals are base ten and do not contain any character other than the digits 0 through 9.¹⁴

3. Real Literals

A real literal (reference production rule 42 of Appendix A) is an unsigned real number. All real literals are base ten. A real number must contain a decimal value (which may be 0), a decimal point ('.'), and a fractional value (which may also be 0). Exponential notation is not allowed.

4. String Literals

A string literal (reference production rule 44 of Appendix A) is any number of characters from the PSDL character set, delimited by quotations ('"'). There are four characters that are not allowed within a string literal: the quotation mark ('"'), the right brace character ('}'), and the format effectors horizontal tab and line feed. PSDL does not specify any limit on string literal length. The empty string is represented as '""'. Strings are case sensitive.

¹³The use of these characters is not recommended.

¹⁴Within the PSDL Editor, integer literals are represented by a C integer data type. In the current implementation, this is a 32 bit value. Only the non-negative values can be represented as an integer literal.

5. Text

Text (reference production rule 49 of Appendix A) can only appear within the description and the axioms structures of PSDL. Within these two structures, text is any number of characters from the PSDL character set, delimitated by braces ('{'} and '}'). Hence, the right brace ('}') can not appear within the text. Any other character, including horizontal tab and line feed, are permitted within the text. Text is the only lexical element that is allowed to cross a line separator.

6. Identifiers

An identifier (reference production rule 41 of Appendix A) consists of a letter, followed by any number of letters, digits, or underscore ('_') characters. All characters of an identifier are significant and are case sensitive. 15

7. Reserved Words

While not addressed in the specification of PSDL [Ref. 3], the implementation of the PSDL Editor utilizes reserved words. A list of these reserved words is provided in Table III. Reserved words can not be used as identifiers within the PSDL prototype. Reserved words differ from identifiers in that reserved words are case insensitive (e.g., OPERATOR, Operator, and operator are all reserved words).

Table IV contains additional PSDL keywords that do not match the syntax of an identifier and hence are not reserved. However, they are still tokens within the PSDL syntax. The symbol '' is used to represent a single space. This single space is part of the keyword and can not be altered by removal, adding of additional spaces, or replaced with a horizontal tab.

In addition to the above keywords (Tables III and IV), PSDL defines a set of identifiers that are available to the prototype developer. This set of identifiers and

¹⁵The PSDL Editor treats identifiers as being case sensitive. Note that Ada identifiers are case insensitive [Ref. 12]. Since CAPS generates control code in Ada it is not advisable to name two identifiers that only differ in case. Moreover, the CAPS Release 2 PSDL Editor will convert all characters of the identifiers to lower-case.

Table III. PSDL Reserved Words

x	Absolute x location of Operator
у	Absolute y location of Operator

identifiers are maintained by the PSDL Editor and are hidden from the user by the PSDL Editor. They will be visible in the PSDL prototype code generated by the PSDL Editor.

8. Delimiters

Delimiters are required to separate adjacent lexical elements. Delimiters include a space character (except when included in a string literal or text), a line feed, or one of the symbols listed in Table VII.

9. Comments

The PSDL syntax does not provide for comments in the sense of comments provided by languages such as Ada. Provisions are made for structured documentation of the prototype. The format and placement of these structures is defined by the PSDL syntax (reference Appendix A). The reserved words **description**, **axioms**, **keywords**, and **required by** are tokens used to introduce documentation into the prototype.

Table VII. PSDL Delimiters

Note that, while **description** and **axioms** constructs facilitate the textual documentation of the prototype, **keywords** and **required** by constructs are restricted to an $\langle id_list \rangle$.

E. PSDL EXECUTION

CAPS provides facilities for executing a PSDL prototype when supported with software components written in an underlying programming language (e.g., Ada) [Ref. 3]. These software components may be obtained from a software base of reusable components or supplied by the prototype developer.

An executable prototype is generated in three steps, available through the Executive Support subsystem of CAPS. Figure 16 depicts the CAPS Release 1 user interface access to these steps¹⁶. The first two steps (i.e., Translate and Schedule) are used to generate the "supervisory" module which provides for control and communication within the prototype. When Compile is invoked, the "supervisory" module along with the packages used to implement the atomic operators and data types are compiled. The prototype is run by invoking Execute.

Translation actually involves two processes. The first process involves flattening the hierarchical structure of data flow diagrams in an expansion process. The

¹⁶Note that this version of the PSDL Editor is in support of the PSDL grammar which will be integrated with CAPS Release 2. This PSDL Editor is not compatible with CAPS Release 1. Comments on compatibility can be found in Appendix B. Execution of a PSDL prototype under CAPS Release 1 is covered here since it is likely that the same steps will still be required with CAPS Release 2.

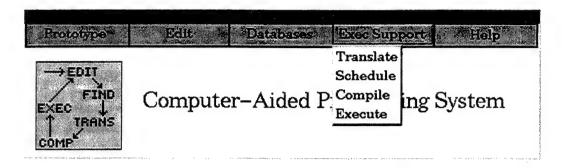

Figure 16. CAPS Release 1 Executive Support

second process is to generate the Ada code required to support the timers, exceptions, stream communication, and control constraints.

The remainder of the "supervisory" module is generated by the scheduler. The scheduler creates a high priority Ada task to control the static schedule (i.e., time critical operators) and a lower priority Ada task to control the dynamic schedule (i.e., non-time critical operators).

All of the generated "supervisory" code is gathered together in one file which is named after the prototype name with an ".a" extension. Which, assuming that the prototype was successfully translated and scheduled, is compiled with the atomic operators and data types. The result is an executable prototype.

III. PSDL SYNTAX/SEMANTIC CONSIDERATIONS

The PSDL Editor is a language sensitive editor with embedded knowledge of PSDL syntax and semantics. The PSDL Editor assists the user by ensuring a syntactically correct prototype, with limited automatic PSDL code generation and limited semantic consistency checking. In the CAPS Release 1 PSDL Editor, this was primarily accomplished by the syntax-directed editor produced by the Synthesizer Generator. The graph editor served two purposes. First, the graph editor was used to present the data flow diagram corresponding to the operator selected in the syntax-directed editor. Second, the graph editor was used to create/maintain the data flow diagram of an operator selected in the syntax-directed editor. Since only the structure, labels, and a few timing parameters of the data flow diagram could be displayed/entered in the graph editor, a simple interface was all that was required to integrate the two segments of the PSDL Editor.

In an attempt to meet the goal of minimizing the artificial boundary produced by implementing the PSDL Editor with both a syntax-directed editor and a graph editor, as well as overcoming the linear constraints resulting from the syntax-directed editor, the user interaction with the syntax-directed editor was to be reduced and the focus placed on the graph editor. As this project is an evolution of the current PSDL Editor, the existing architecture of a syntax/semantics checker and a graph editor was maintained. With the user's focus being placed on the graph editor, an expanded interface was required between the syntax/semantics checker and the graph editor. This change in focus also required a redistribution of the embedded syntax and semantic knowledge between the two editor segments.

This research concentrated on the development of the graph editor. The syntax/semantics checker was implemented as an Ada program, referred to as the background checker, in a parallel development effort by Professor Man-Tak Shing. The

Table VIII. PSDL Interface Structures Summary

Structure	Description	Direction
GRAPH_DESC	Representation of a single operator plus	$SDE \leftrightarrow GE$
	some "global" data.	
ERROR_MSGS	Semantic errors detected by the syntax-	$SDE \rightarrow GE$
	directed editor.	
ACTION	Control requests for next action to be	$SDE \leftarrow GE$
	taken by the syntax-directed editor.	

integration of the the background checker and the graph editor was a shared task. In order to accomplish this parallel development, a new interface was established. Unlike the interface which was utilized in the CAPS Release 1 PSDL Editor, which shared a minimal set of data flow diagram data, this interface shared the complete specification of a single PSDL operator. Additional data was shared to provide "global" prototype information to the graph editor was well as to support control functions. The interface was defined by the file ge_interface.h (reference the source listing of ge_interface.h found in Appendix D on page 195).

Figure 17 depicts the interfaces of the PSDL Editor. External interfaces to the PSDL Editor provide for the reading/writing of the PSDL code as well as for user interaction with the editor through the Graphical User Interface. Internally, all editor segment communication is performed through the ge_interface.h data structures, represented by the dashed box inside the PSDL Editor of Figure 17. The ge_interface.h file contains three structures used to organize communications between the background checker and the graph editor. These structures are summarized in Table VIII.

The GRAPH_DESC interface accommodates the representation of a single PSDL operator. This is symbolized by the box around operator d with an arrow pointing to the GRAPH_DESC data structure in Figure 17. The interface does not support the

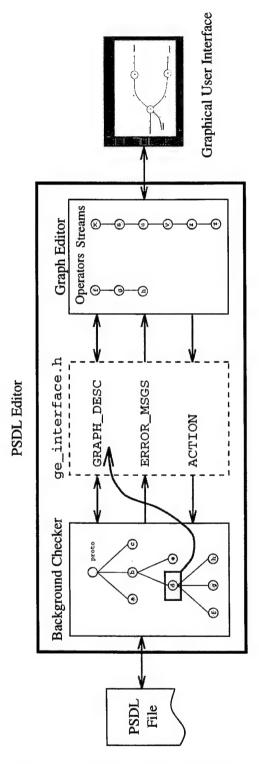

Figure 17. PSDL Editor Interfaces

PSDL representation of the operator¹⁷. Instead, coming from a PSDL file, the PSDL code is parsed by the background checker and attribute values are stored in the prototype data structure, local to the background checker. PSDL reserved words are removed. The association of an attribute value with a PSDL construct is provided implicitly in the data structure. In the other direction, coming from the Graphical User Interface, attribute values entered by the user are associated with, and stored into, the GraphObjectList data structure, local to the graph editor. It is not until the prototype is written to disk by the background checker that the attribute values are mapped into PSDL code.

A. SYNTAX AND SEMANTIC KNOWLEDGE DISTRIBUTION

Since only a representation of the PSDL operator is shared between the background checker and the graph editor, the majority of the embedded syntactical knowledge must reside in the background checker. The background checker is responsible for the input parsing of a PSDL prototype as well as the generation of the PSDL code, which is the output of the PSDL Editor. The syntactical knowledge embedded within the graph editor is limited to that required to validate the user supplied data values associated with a PSDL construct and limited, locally-scoped, semantic validation.

A syntactically correct PSDL prototype is ensured in a two step process. First, all user supplied data values are validated prior to acceptance into the graph editor's data structures. Second, all PSDL code is generated by the background checker, based on the inputs provided by the user from the graph editor.

It is critical that the PSDL Editor generate syntactically correct prototypes. No matter what stage of a prototype's development, the prototype must be syntactically correct. All viewing/editing of a prototype is accomplished from the graph

¹⁷The ge_interface.h accommodates some PSDL code in order to facilitate the editing of selected PSDL constructs which were too complex for the initial implement of the graph editor's user interface. This includes all PSDL types and expressions.

editor. The graph editor does not receive or transmit the PSDL code. The code is encoded into the GRAPH_DESC data structure by the background checker. The background checker is only capable of encoding the PSDL code into the internal data structure representation if it can parse the code. Currently, the background checker does not have any provisions for error correction of a syntactically incorrect prototype. The CAPS PSDL Editor can not be used to edit a syntactically incorrect prototype.

The graph editor is embedded with a limited amount of PSDL semantic knowledge. Semantic consistency is primarily accomplished by limiting the user's options to those that are semantically correct. The graph editor is limited to semantic issues that are local to an operator. The interface between the background checker and the graph editor is limited to a single operator. All global semantic issues are resolved by the background checker.

Note that while a prototype which is not semantically correct can not be translated and executed by the Execution Support tools, it is not necessary that the prototype be semantically correct to be edited with the PSDL Editor. There are potential semantically incorrect prototypes which are not compatible with the PSDL Editor. However, there is no general limitation against semantically incorrect prototypes as there are with syntactically incorrect prototypes.

B. USER SPECIFIED PSDL CONSTRUCTS

It is the graph editor that provides the user interface for PSDL Editor. The graph editor does not understand PSDL syntax. Instead, the graph editor deals with a small collection of data objects from which a PSDL construct is built. It is the data objects provided by the user which are properly formatted with PSDL reserved words by the background checker to produce a PSDL prototype (i.e., PSDL code). The data types which must be supported by the graph editor can be derived from the PSDL grammar (reference Appendix A). Table IX lists the fundamental data objects which must be supported by the graph editor. Production rules provided in Table IX

Table IX. Fundamental PSDL Data Objects

PSDL Data Object	Defining Production Rule
id	41
id list	11
operator id	24
type name	10
integer literal	43
text	49
enumeration	

Table X. Enumeration Values

Enumeration Usage	Enumeration Values, separated by 'I'
Operator Type	Operator Terminator
Implementation Language	ADA TAE Others
Trigger	unprotected By Some By All
Timing	Non-Time Critical Periodic Sporadic
Time Literal Units	microsec ms sec min hour
State Stream Selection	Yes No

refer to those specified in Appendix A which define the syntax of the data object.

Enumeration values are provided in Table X. Some of the enumeration values correspond to PSDL reserved words. However, some are used to free the user from implementation details of PSDL. For instance, the operator type (i.e., Operator | Terminator) does not correspond to any PSDL construct. The selection of a Terminator is encoded by setting the Maximum Execution Time of the operator to zero. In this case, the use of an enumerator, along with semantical knowledge embedded in the graph editor, are used to hide this implementation detail of PSDL from the user.

There were specific PSDL constructs which were deemed too complex to be provided in the initial implementation of the graph editor's user interface. Table XI lists those constructs for which syntactical knowledge was not embedded in the graph

Table XI. Complex PSDL Data Objects

PSDL Data Object	Defining Production Rule
data type	3
interface	7
constraint options	29
expression	39
initial expression list	32

editor. In order to provide full functionality within this version of the editor, separate syntax checkers are provided for these constructs. The graph editor provides a text window from which these constructs may be viewed/edited¹⁸.

C. HIERARCHICAL STRUCTURE

A PSDL prototype is implemented as a network of operators, which may or may not be connected. Syntactically, a PSDL prototype is simply a set of operators¹⁹. A given operator consists of a specification and an implementation construct. It is the data flow diagram, contained in the operator's implementation, which describes the prototype network. The prototype network itself is decomposed in a hierarchical manner, described by a tree, in which each operator can be described by its own network of PSDL operators.

Figure 18 depicts the skeleton of a PSDL prototype²⁰. The prototype consists of nine operator components. The implementation construct of the root operator, proto, identifies the first level of vertices (i.e., operators) and edges (i.e., streams)

¹⁸Syntactical validation of these constructs is required in order to maintain a syntactically correct prototype. As of this writing, this facility has not yet been provided.

¹⁹Actually, a PSDL prototype is a set of operators and abstract data types. However, it is only the operators, which includes operators of an abstract data type, which are executed. For this discussion, we will consider operators only.

²⁰The code presented here does not conform to the CAPS Release 2 semantics. In order to simplify the example, the unique identifier suffixes have been deleted. The unique identifier suffixes will be introduced later in this chapter.

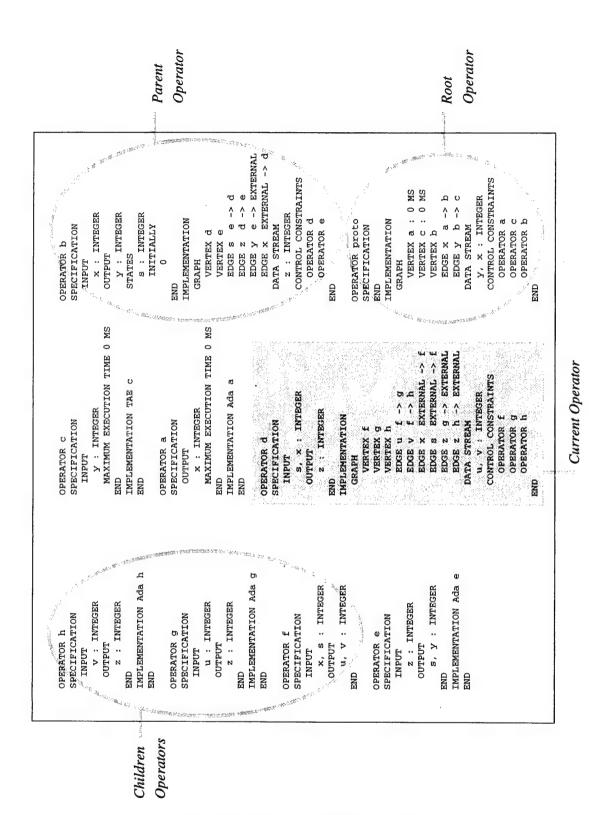

Figure 18. Sample PSDL Prototype

which constitute the prototype network. Each operator identified in this network is contained in the PSDL prototype, the implementation of which may or may not be described as a network of PSDL operators. Figure 19 provides a corresponding hierarchical representation, along with a simple tree representation, of the PSDL prototype provided in Figure 18.

Note that, while the decomposition of the PSDL network is represented as a tree, the PSDL network itself is not restricted to a tree. In general, the PSDL network can be implemented as a disconnected graph containing cycles. Figure 20 depicts how the prototype tree structure is flattened into the PSDL network, which implements the prototype, proto. For each level of the tree, the resulting PSDL network is provided. The resulting network is representative of the outcome of the flattening process used by the Execution Support tools. While the original network of Figure 18, described by operator proto, was a simple tree consisting of three vertices, the flattening of the PSDL network resulted in a connected graph of six vertices containing a cycle.

The tree describes the relationship between operators, not the communication paths between operators. In Figure 18, operator d has been selected as the current operator of interest. From Figure 19, it can be seen that operator b is the parent and that operators f, g, and h are the children. Operator proto is the root operator.

Within the background checker, the entire PSDL prototype is maintained. The interfacing data structure, GRAPH_DESC (contained in ge_interface.h, reference Appendix D, page 195), only facilitates the representation of one operator. The current operator being edited is selected by the user, in a process of navigating through the prototype tree structure. Initially, the root operator is selected by the PSDL Editor as the current operator.

Thus, for the prototype depicted in Figure 18, all nine operators would be maintained simultaneously within the background checker's data structures. Within the graph editor, a single operator, such as the data represented by the shaded rectangle (operator d) in Figure 19, would be maintained. Initially, the operator proto

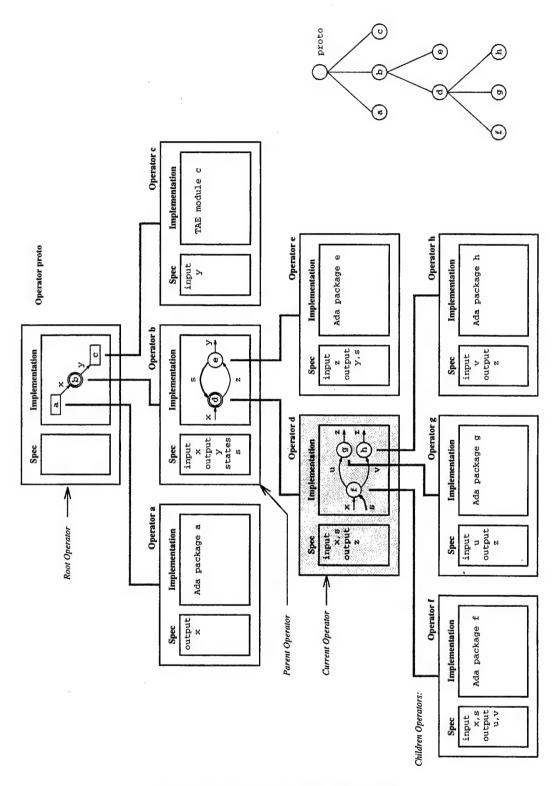

Figure 19. Sample PSDL Hierarchy

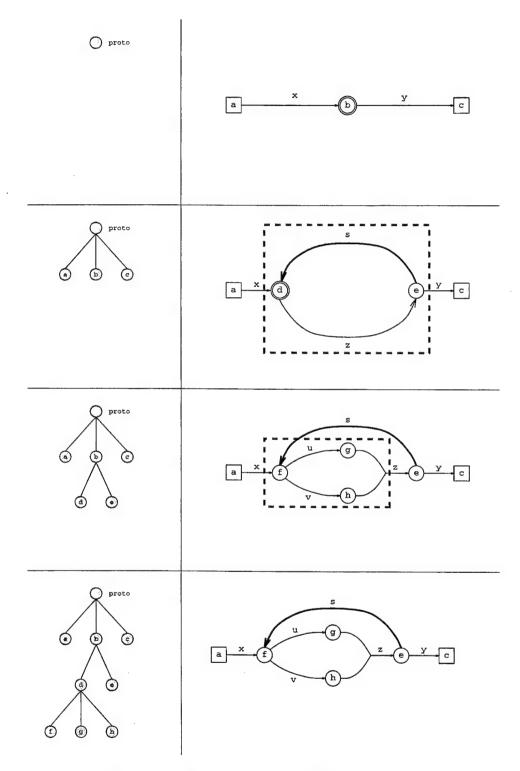

Figure 20. Flattening of the PSDL prototype

would be presented to the user by the graph editor. As the user navigates through the operator tree, the operator represented in the graph editor data structures is replaced with the operator selected by the user. It is the responsibility of the background checker to extract and relay the information for the current operator to the graph editor.

From a graph editor perspective, at most four levels of the prototype tree are relevant at any given time. It is the responsibility of the background checker to orchestrate the data of these four levels with the information contained in the GRAPH_DESC data structure. These four levels are represented in Figure 21, in which the graph editor has no visibility into the shaded regions²¹. The operator of interest is the current operator. This is the operator which is being edited. Both the specification and the implementation constructs of the current operator are available for viewing and editing. One level down from the current operator are the children operators. Portions of the specification construct of the child operator are available for viewing and editing. The input/output constructs of the child's specification are derived from the current operator's data flow diagram. The functionality constructs of the child's specification are also made available through the editing of operator options in the current operator's data flow diagram. Also available from the operator options is the implementation language of the child operator. One level above the current operator is the parent. The parent operator is used by the background checker to derive the current operator's specification construct (i.e., the input and output constructs). The parent operator is not directly visible from the graph editor. The final level which is visible is the root level. The actual root operator is not visible (unless it is the current operator). However, the root level contains global information, which is visible from any level. Specifically, abstract data types are global to the prototype and are visible from any level of the prototype tree.

²¹Note that, while the graph editor may have visibility into a region which is not shaded, the graph editor does not necessarily have the ability to write to an area that is not shaded. Much of this visibility is provided by the background checker providing derived information on the prototype.

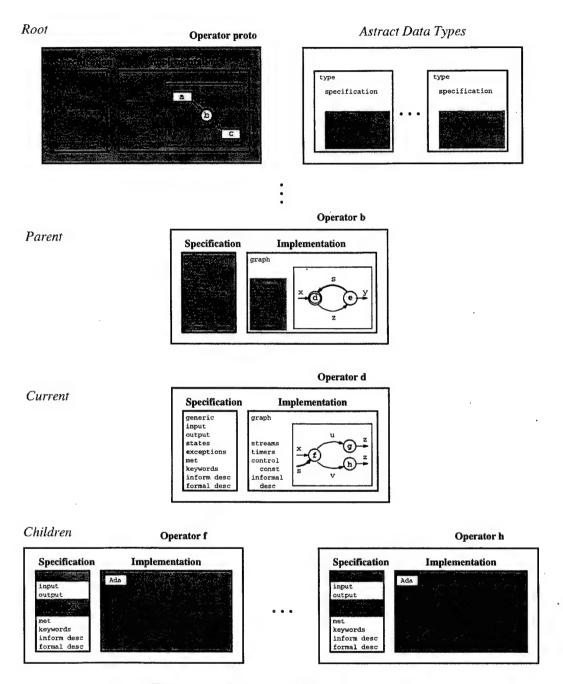

Figure 21. Relevant PSDL Tree Levels

The background checker is responsible for deriving the values to be inserted into the GRAPH_DESC data structure. Figure 22 provides the GRAPH_DESC data structure ture extracted from ge_interface.h. Within the GRAPH_DESC data structure, the background checker provides several references to the prototype levels just discussed, starting with the current operator being identified by cur_op_name and cur_op_num. From this starting point, all children are readily available through the data flow diagram. However, the parent can not be derived from the current operator. The background checker provides a reference to both the parent_op_name and parent_op_num, as well as the root, root_op_name and root_op_num.

The current operator's specification is supported using several symbols. The cur_op_spec provides the PSDL code. The specification construct must be derived by the background checker. The input and output constructs are derived from the parent operator's data flow diagram. This was seen in Figure 19, where the input and output streams of operator d could be derived from the data flow diagram of the parent operator, operator b. In this case, streams x and s were the input streams and z was the output stream. In order to minimize the PSDL syntactical knowledge required by the graph editor, the background checker provides a partial parsing of the operator's specification. The operator's input stream list, input_list, output stream list, output_list, and maximum execution time, cur_op_spec_met and cur_op_spec_met_unit, are all provided as objects which can be operated on by the graph editor. Note that a portion of the current operator's specification is dependent upon the current operator's implementation. For example, the list of states provided in the specification are derived from the current data flow diagram. For such cases, the PSDL code provided in cur_op_spec is not maintained while in the graph editor. The background checker will update these constructs as requested.

The current operator's implementation is composed of several objects. The majority of the operator's implementation is provided in the data flow diagram. In addition, a list of timers, timer_list, and the data flow diagram's informal descrip-

```

```

Figure 22. GRAPH_DESC Extract

tion, graph_informal_desc, are supported. The operator's data flow diagram is specified by a linked list of operators, operator_list, and a linked list of streams, stream_list.

All abstract data types are provided as PSDL code in global_types. This implementation of the graph editor does not provide graphical user interface support of abstract data types. However, the PSDL code, as derived by the background checker is made available to the graph editor.

Upon returning control back to the background checker, the ge_interface.h data structures are used to update the PSDL prototype components. Primarily, this involves updating the current and child operators. However, global updates of components may be required to maintain consistency with changes introduced in the current operator.

D. PSDL VALIDATION AND GENERATION

The PSDL Editor ensures a syntactically correct prototype. In the CAPS Release 1 PSDL Editor, all of the syntactical knowledge was embedded in the syntax-directed editor. This was appropriate since, other than the data flow diagram, the prototype was edited through the syntax-directed editor. With the focus of this implementation being on the graph editor and the graphical user interface, the prototype is now fully defined from the graph editor. Even with this change of focus, it is still possible to maintain the majority of the syntactical knowledge within the background checker. However, with the editing of the prototype being accomplished in the graph editor and the syntactical verification being performed in the background checker, a time delay is inserted between the entry of the prototype data and the detection of any errors. The length of this time delay is dependent upon how the graph editor and background checker interface. In the CAPS Release 1 PSDL Editor implementation, the syntax-directed editor generated by the Synthesizer Generator performed incremental validation of PSDL syntax as the user typed [Ref. 8]. For this

implementation, the interface between the background checker and the graph editor is accomplished similar to batch processing. In this mode of operation, an operator is edited without assistance from the background checker. Upon the user request to verify the prototype, or upon changing the current operator to another operator, the background checker is called to perform syntax/semantic validation.

There are two categories of errors which are detected by the PSDL Editor: syntactic and semantic. With automatic PSDL code generation by the background checker, syntactical errors are limited to user supplied input. Semantic errors are generally more global, typically involving one or more operators. Typically, semantic errors which are detected are based on a relationship between two symbols. With this distinction between the nature of the two categories of errors, it seemed reasonable to move the detection of syntactical errors to the graph editor, avoiding any delays introduced with a batch mode of operation, while semantic error detection being performed within the background checker. With the current architecture of the background checker and the graph editor, certain semantic errors can only be detected from the background checker, since only the background checker has a global perspective of the prototype.

In addition to the generation of the PSDL constructs associated with user supplied inputs, the PSDL Editor supplies automatic code generation for redundant data. This feature is most apparent in the generation of PSDL code to support both the specification and implementation constructs of an operator.

1. Validation of PSDL Constructs by the Graph Editor

The graphical user interface of the PSDL Editor facilitates the validation of user supplied PSDL constructs. Validation of user inputs are performed prior to updating the graph editor internal data structures. In this manner, all user supplied inputs are validated prior to being relayed back to the background checker. All fundamental PSDL data objects listed in Table IX are validated by the graph editor. Table XII provides the routines and state machines, as applicable, in which the funda-

Table XII. Fundamental PSDL Data Object Validation

PSDL Data Object	Rule	State Machine	Routine

type name	10	Figure 24	valid_type_name
integer literal	43	N/A	valid_integer_literal
text	49	N/A	Motif
enumeration			Motif

mental data objects are validated. Validation routines are found in ge_utilities.c, which is included in Appendix D, starting on page 202. All enumeration values listed in Table X are validated by the graphical user interface by only allowing the user to select one value from a predefined list.

For the complex PSDL data objects listed in Table XI, the graph editor does not contain the syntactical knowledge to validate user supplied input. While required,

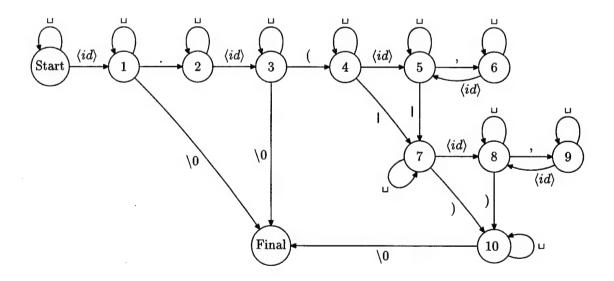

Figure 23. $\langle op_id \rangle$ Validation State Machine

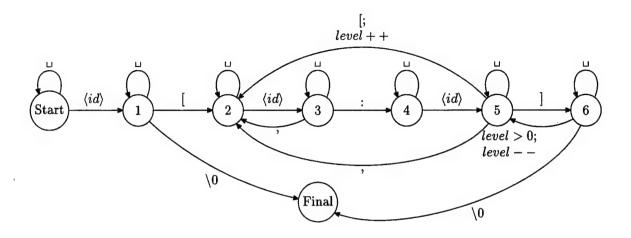

Figure 24. \(\langle type_name \rangle \) Validation State Machine

the facilities needed to provide this validation have yet to be implemented.

2. PSDL Redundant/Derived Data

The operator's specification defines the external interface of the operator while hiding the details of the implementation. The specification provides a "summary" of the operator, and thus contains redundant information found in the operator's implementation. The PSDL Editor provides support for this redundant information. The user is only required to enter data once. The background checker is equipped with the semantic knowledge required to derive the redundant data. In addition to saving the user from entering redundant information, this implementation avoids semantic errors due to inconsistencies between redundant data. If data is entered twice, there is the possibility that it will be inconsistent. If it is only entered once, there is no possibility for inconsistent data.

The graphical user interface designed for the graph editor has been limited to the single entry of redundant data. There is no semantic knowledge regarding redundant data in the graph editor. All redundant data processing is performed by the background checker.

3. PSDL Semantic Consistency by the Graph Editor

While limited by the local scope of a single operator, the graph editor is still capable of enforcing some semantic consistency.

Within the scope of an operator, those operators used to implement the data flow diagram must be unique. Uniqueness of operator labels does not apply to operators of an abstract data type. Uniqueness is enforced upon user entry of the operator label. The routine unique_op_id, found in graph_object_list.C (reference Appendix D, starting on page 277), is used to test for uniqueness.

The characteristic of an operator being implemented as a composite terminator (i.e., having a maximum execution time of zero) is inherited by all operators of the data flow diagram. The graph editor enforces this inheritance by limiting the user to the use of only terminators within the graphical user interface.

Unlike the scoping rules for operator labels, which must be unique for non-type operators within a data flow diagram, multiple uses of a stream are allowed within a data flow diagram. While each operator implements its own type of stream (i.e., data flow stream or sampled stream), streams also contain global characteristics. These include stream type, state stream, and initial value. The graph editor provides for the propagation of these characteristics for all streams within the data flow diagram. It is the requirement of the background checker to maintain consistency of these global characteristics external of the current operator. The graph editor enforces consistency through the routine propagate_stream, found in graph_object_list.C (reference Appendix D, starting on page 277).

With a global perspective, the background checker is capable of providing additional semantic validation. Specifically, the background checker has provisions for validating the input and output streams specifications in a child/parent relationship. As was seen previously in Figure 19, the data flow diagram of the parent operator defines the inputs and outputs to the child operator. When a child operator is implemented with a PSDL network, the external input and output streams present in the

child's data flow diagram must exactly match the input and output streams found in the parent's data flow diagram [Ref. 3]. External input and output streams which were not defined in the parent's data flow diagram are flagged as being illegal by the background checker. Input and output streams defined in the parent's data flow diagram but missing from the child's implementation are flagged as being missing.

In these two cases, it is beyond the capability of the PSDL Editor to determine a corrective action. Instead, upon detecting the error, the background checker provides an error message to the user. Facilities are provided to navigate directly to the parent or child operator in order to correct the problem.

The background checker provides an additional test to warn against a semantic violation. As was previously mentioned in Chapter II, PSDL has no global variables. However, as currently implemented in CAPS Release 1, streams are global, based on the stream name. The background checker tests for the use of global streams and provides a warning on its use.

Figures 25 through 27 provide an example of these error conditions which are detected by the background checker. Figure 25 provides the parent data flow diagram. Figure 26 provides the decomposition of operator b found in the parent's data flow diagram. Figure 27 depicts the resulting error messages from this prototype. In this case, the parent's data flow diagram specifies that operator op_b shall have an input, op_b_in, and an output, op_b_out. Within the implementation of operator op_b, found in Figure 26, two undefined, external streams are specified, called in and out. These two errors are reported as the first two errors in Figure 27. Next, the lack of input op_b_in and output op_b_out from the child's implementation are reported as the next two errors in Figure 27. Finally, the global stream x is defined both in the parent's data flow diagram and the child's data flow diagram, without the stream being passed between the parent and the child. The final two error messages of Figure 27 report this condition.

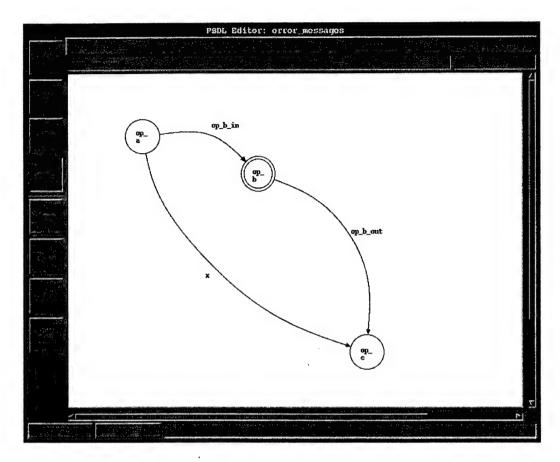

Figure 25. Parent Graph Depicting Errors

E. PSDL SYNTAX CHANGES

Several modifications have been made to the PSDL grammar in support of CAPS Release 2. The new PSDL Editor is required to support these changes. A copy of the CAPS Release 2 PSDL grammar is provided as Appendix A. A few small fixes have been incorporated, such as updates to the $\langle letter \rangle$ and $\langle alpha_numeric \rangle$ production rules. Previously, these rules allowed any number of consecutive underscore characters ('_') in an $\langle id \rangle$. The grammar rules have been changed (reference production rules 47 and 48 in Appendix A) to be consistent with the construct of identifiers in Ada. Another small change was the generalization of the implementation language identifier in the $\langle type_impl \rangle$ and $\langle operator_impl \rangle$ production rules (reference rules 17

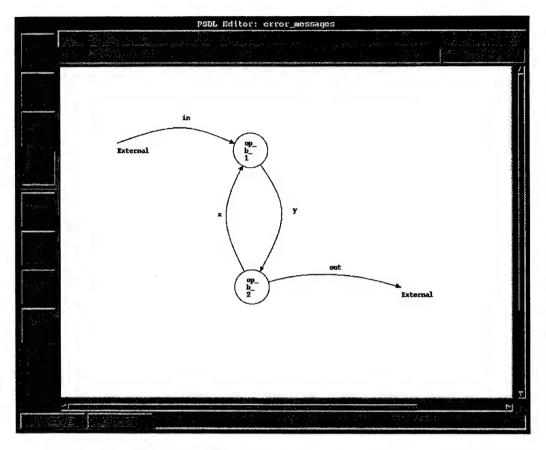

Figure 26. Child Graph Depicting Errors

and 18 in Appendix A). Previously, only Ada was allowed as an implementation²².

Two more substantial changes were made to the PSDL grammar which impact the PSDL Editor. From the standpoint of the user interface, these changes are transparent to the user. However, both require support from the PSDL Editor to implement.

1. PSDL Data Flow Diagram Properties

In CAPS Release 1, the PSDL file generated by the PSDL Editor was sufficient to support the Execution Support tools, yet was not sufficient to support the PSDL

²²Currently, the only supported implementation languages are Ada and TAE. Facilities have been provided in the grammar for future supported languages.

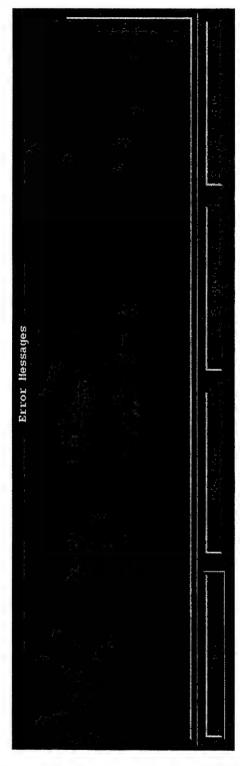

Figure 27. Syntax-Directed Editor Error Messages

Editor. The PSDL Editor provided an additional file, with an extension of ".grf", to facilitate the presentation of the data flow diagram. In CAPS Release 1, the PSDL grammar did not have provisions to capture the full specification of the data flow diagram (i.e., the visual presentation requirements). In CAPS Release 2, the PSDL grammar has been updated with a property construct (reference production rules 21, 22, and 23 in Appendix A) for this purpose. This change provides for the tagging of properties to vertices and edges of a data flow diagram based on predefined identifiers. These properties capture the information which was previously recorded in the ".grf" file. A list of these identifiers was provided in Chapter II as Table VI (page 38). Currently, these properties are only used by the PSDL Editor.

2. Unique Identifier Suffixes in CAPS Release 2

CAPS Release 2 introduced a new semantic convention for the purpose of enforcing PSDL scope rules. Professor Berzins described the conventions used in his email dated 25 July 1996, which has been provided as Appendix C.

The semantics of PSDL requires that the operators within a composite PSDL operator (i.e., an operator which has been implemented with a PSDL network) be local to that operator. The scoping of operators is illustrated in Figure 28, a portion of a PSDL prototype, in which operators fm_a and fm_b both contain operators with common names, x, yet are local to their respective parent operator. However, this only applies to PSDL operators. Scoping for operators of a PSDL type are global, as PSDL types are globally available within the prototype heirarchy. Thus, t.x refers to the same operator of t, from both fm_a and fm_b. Note that within an operator, PSDL operator names must be unique, as was described previously.

In order to implement the PSDL scoping rules, unique integer suffixes are attached to the PSDL operator identifiers, thus ensuring that all PSDL operators are unique. In addition to supporting the scoping rules of PSDL operators, suffixes are also used to support multiple instances of PSDL type operators within the same graph. Thus each operator, both PSDL operators as well as PSDL type operators,

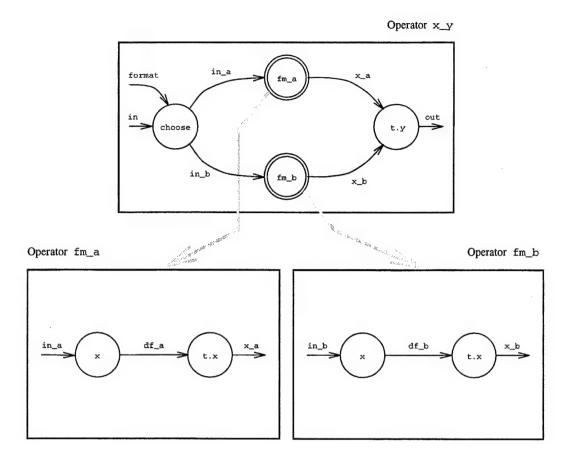

Figure 28. Scope of PSDL Operators

are assigned a vertex number within a data flow diagram. In addition, each PSDL operator is assigned an operator number. The convention is as follows:

```
\langle op\_name \rangle \_ \langle op\_num \rangle \_ \langle vertex\_num \rangle
\langle type\_op\_name \rangle \_ \langle vertex\_num \rangle
```

The above prototype portion is depicted again in Figure 29, in which suffices have been included.

Note that this is actually not a syntax change. The inclusion of operator and vertex number suffixes is within the syntax of an $\langle id \rangle$ (reference production rule 41 in Appendix A). The use of suffixes to implement the PSDL scoping rules is a semantic convention which is used by the CAPS subsystems. The implementation of the suffix

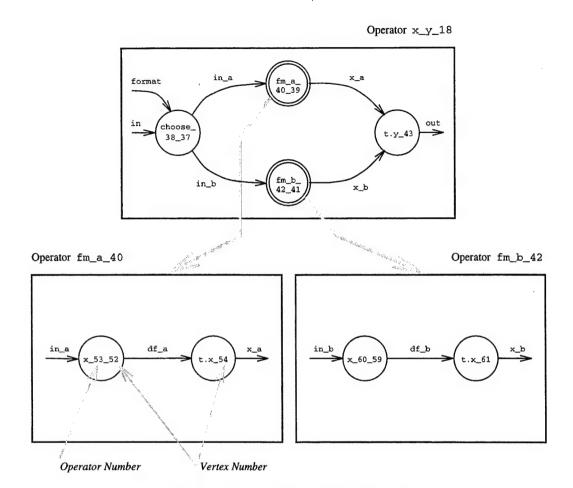

Figure 29. PSDL Operator Suffixes

convention is to be hidden from the PSDL Editor user, thus requiring the PSDL Editor to fully automate its suffix behaviour.

IV. USER-INTERFACE DESIGN

The core of a PSDL prototype is the data flow diagram. In the CAPS Release 1 PSDL Editor, the graph editor was solely used to edit/view the data flow diagram. Following the editing of the data flow diagram, the syntax-directed editor was used to edit all other constructs of the prototype. This release of the PSDL Editor attempts to streamline the editing process of a PSDL prototype by focusing the user interaction to the graph editor.

From an inspection of the PSDL grammar (reference Appendix A), it can be seen that a large number of PSDL constructs can be synthesized by the editor, using simple user provided data objects (e.g., literal values, text strings, identifiers, and list of identifiers). As a PSDL prototype consists of a network of operators connected by streams, the PSDL constructs, and hence the user provided data objects, are all associated with either an operator or a stream. The only exception being abstract data types. Thus, a graphical user interface model was developed, which build upon the earlier data flow diagram effort of the CAPS Release 1 graph editor, with the addition of pop-up windows associated with operators and streams for the entry of user provided data objects.

Complex PSDL constructs (e.g., expressions), as discussed in Chapter III, are associated with operators and streams as well. However, the complexity of these constructs does not lend themselves to a simple synthesis from user provided data objects. As an initial attempt of expanding the graphical interface of the PSDL Editor, the specification of these constructs was maintained in PSDL syntax.

A large portion of the graphical interface produced by Captain Robert Dixon, USMC [Ref. 13], was maintained in this implementation. Primarily, the interface used for the data flow diagram was preserved, with a few enhancements. Expansion of the graphical interface was partially outlined as part of the NPS CS4520 (AY96Q4) class project, implemented by Mr. Douglas Lange and Mr. Dagohoy Anunciado.

Additional modifications and enhancements to the interface were a result of this research.

A. PSDL EDITOR ENVIRONMENT

The graphical user interface provided in CAPS Release 1 (i.e., the graph editor's interface) was built upon the X Window System²³, using the Motif²⁴ widget set. The selection of Motif for use in the CAPS Release 1 PSDL Editor was discussed in Captain Dixon's thesis [Ref. 13]. Motif provides assistance in the development of an application by providing a standard look and behavior to the user interface.

1. PSDL Editor Layout

The PSDL Editor's graphical user interface is designed to facilitate the specification of a PSDL operator. As was discussed previously, the user interface is limited to a single PSDL operator at any given time. The PSDL Editor does not provide for the implementation language (e.g., Ada) editing of an operator.

The PSDL Editor's graphical user interface is depicted in Figure 30. The graphical user interface consists of six areas, which are identified in Figure 30 and discussed in the following paragraphs. Pop-up windows are used to support the specification of constructs directed at streams and operators of a data flow diagram.

a. Main Window

This is the X Window from which the user interacts with the PSDL Editor. The MAIN WINDOW is equipped with a title along with several control widgets on the top bar. The title is composed of "PSDL Editor:" and the name of the prototype. The prototype name is based on the file name (i.e., name of root operator) provided upon execution of the PSDL Editor. If no file name is provided, the title is set to DEFAULT_PROTO_NAME. The operation of the control widgets is based on the X

²³X Window System is a trademark of the X Consortium.

²⁴Motif is a trademark of the Open Software Foundation.

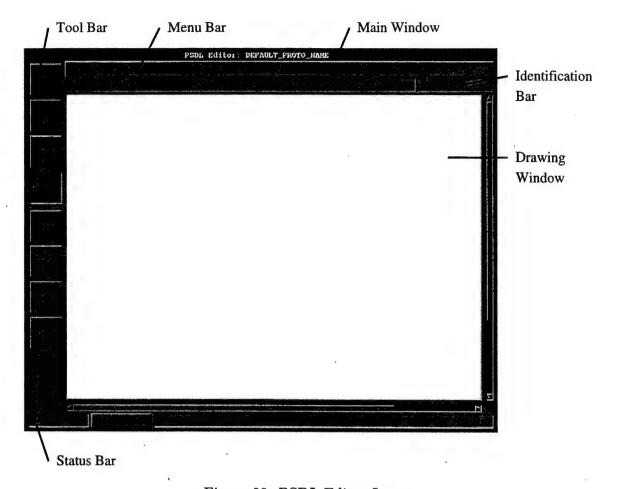

Figure 30. PSDL Editor Layout

Window System initialization. Reference Appendix E for notes on customization of the Main Window.

b. Menu Bar

Pull-down menus provide easy access to PSDL Editor functions. Standard access to the pull-down menus is supported, accomplished using the left-mouse button. Figure 31 depicts all four pull-down menus. Note that the MENU BAR was distorted in the generation of this figure in order to display all four menus simultaneously. Only one menu is available at a time in the PSDL Editor.

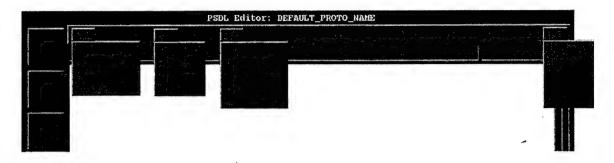

Figure 31. PSDL Editor Menus

c. Tool Bar

The TOOL BAR is divided into two areas by a horizontal line. Above the line, buttons are provided to access tools for "drawing" the data flow diagram. Below the line, buttons are provided to access functions for editing several PSDL constructs. The functions provided here are relative to the current operator or are global in nature (e.g., the function Types is directed towards abstract data types). As will be seen later, other functions, available through pop-up windows, are relative to the operators and streams contained in the data flow diagram. The functions here (i.e., Spec, Timers, and Graph Desc) are directed to the operator indicated in the Identification Bar.

The selected drawing tool, above the horizontal line, is independent of any tool selected below the horizontal line. While drawing functions are not active during the use of a tool below the horizontal line, upon exiting, the previously selected drawing tool remains in effect until another drawing tool is selected.

d. Identification Bar

The IDENTIFICATION BAR provides the name of the current operator (left data window) as well as the maximum execution time of the current operator (right data window). These values can not be modified at this level. Instead, the user is required to change the values from the parent operator's data flow diagram. The values displayed from the root operator can not be changed.

e. Drawing Window

This area is used to display/edit the data flow diagram. Scroll bars are provided as necessary to view the entire data flow diagram window. Beyond the area accessed through the window scroll controls, the Drawing Window can not be enlarged. If a larger drawing area is required, consider decomposing operators.

f. Status Bar

The STATUS BAR provides feedback to the user. Divided into three windows, the STATUS BAR provides: (1) an indication that the prototype has been modified (SAVE REQUIRED versus SAVE NOT REQUIRED), (2) an indication that the prototype's syntax should be verified (CHECK SYNTAX versus ERROR MSGS), and (3) a window for displaying status and error messages.

The first two indicators are button widgets. The labels on the buttons are changed as required to provide feedback. Activation of the button provides a short cut to the desired function (i.e., save the prototype, perform a syntax check, and display any error messages). The last indicator provides an area to provide editor feedback. Typically, an information pop-up window is used to display an editor message. This window is used to remind the user after the pop-up window has been acknowledged. The window is automatically erased, typically on the next operation.

2. Component Identification

From the Main Window, the user can access an Operator Property or Stream Property pop-up window. This is accomplished by positioning the cursor over an object in the Drawing Window and pressing the right-mouse button. The appropriate pop-up window will be accessed. Figures 32 through 34 provide an example of the these three windows. Component²⁵ Identification numbers are provided, which reference into Table XIII (Index), providing identification of all displays/controls.

 $^{^{25}}$ In this case, component refers to a Motif widget and not to a PSDL component.

3. Types of Components

Under the Component Type column of Table XIII, the various types of user interaction are identified. The PSDL Editor utilizes a limited set of widgets to interact with the user. These components are used both for editing a data object as well as viewing a data object. Typically there is not sufficient space within a window to view all of a data type. Controls are used to access additional Motif widgets from which the entire data object can be viewed/edited. In most cases, an indication is provided that additional information is available through a pop-up window.

The data flow diagram requires significant interaction. It will be discussed in another section.

a. Display Only

This widget provides no input/control functionality. It is only used to display data. Data may be obtained from the editor and displayed, as is the case for the Current Operator Name (Index 5). Alternatively, the input may be provided by the editor, but accessed from a control button, as in the case of Trigger Id Condition Expression (Index 26) which is accessed from the Trigger If Condition (Index 25).

b. Data Entry

This widget provides direct data entry through the keyboard. Prior to data entry, ensure that the mouse cursor is positioned within the Data Entry window. The user can scroll through the Data Entry window using the left and right arrow keys, as required.

c. Select

This widget provides a select-one-of function. Values act similar to an enumeration type. Values are predefined and only one value can be selected. The Select type may be either a radio widget, such as State Stream Selection (Index 50), or a pull-down version, such as Implementation Language (Index 22). The pull-down version is activated by depressing and holding the left-mouse button over the component. Move the cursor over the desired value and release the mouse button. An example of the Implementation Language widget is provided in Figure 35. Note

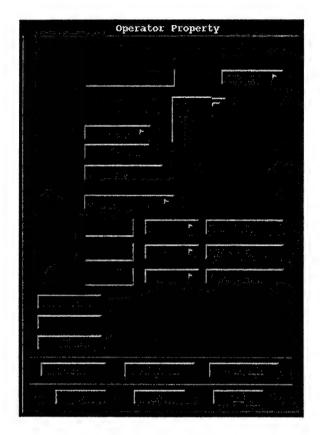

Figure 35. Select Component

that, in this example, the cursor is not visible.

d. Control

Control widgets are accessed by depressing the left-mouse button over the component.

e. Control-Text

Control-Text components access a pop-up Text window. An example of a Text Window is provided in Figure 36, in which the prototype's abstract data types were accessed through the TYPES TOOL (Index 14).

Within the Text Window, the user can position the cursor with the mouse and edit the text. The cursor must remain within the Text Window while editing the text. Scroll bars are provided for moving through the text. Initially, all changes made within the Text Window are local to the Text Window. In order

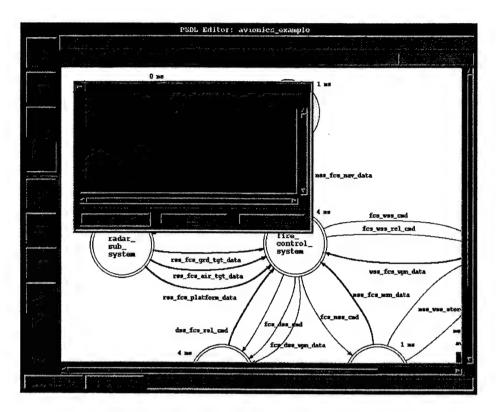

Figure 36. Text Window Component

to modify the prototype, the changes must be accepted. This is accomplished by depressing the OK button. Changes may be aborted by depressing the CANCEL button.

f. Control-IdList

Control-IdList components access a pop-up identifier list editor. Within this window, a list of identifiers may be viewed/edited. An example of an Id List Window is provided in Figure 37, in which the operator's Timer list is accessed through the Timers Tool (Index 16).

From the Id List Window, the identifier list can be viewed directly. In order to add an identifier, the Add button is depressed. A pop-up window is provided to add the identifier to the list. The new identifier is accepted locally through the OK button. The addition of an identifier to the Id List is depicted in Figure 38. A similar

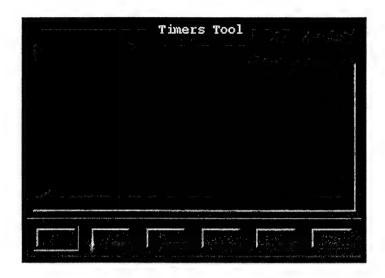

Figure 37. Identifier List Editor Component

process applies to the editing of an existing identifier. However, in the case of editing an identifier, the identifier must first be selected. Otherwise an information message will be displayed to select an identifier first. In order to delete an identifier from the list, select the identifier and depress Delete. Again, an information message will be displayed if an identifier is not first selected.

Like the Text Window, initially, all changes made within the Id List Window are local. In order to modify the prototype, the changes must be accepted. This is accomplished by depressing the OK button. Changes may be aborted by depressing the Cancel button.

4. Display Indications

Under the Indicator column of Table XIII, the various methods used to display data are identified. Where practical, data objects are displayed within the window. However, due to the limited space within a window, it is not always possible to display the entire value of a data object. An effort was made to indicate to the user where data is available. This is not universal, in that the tool buttons have no indication of the existence of data.

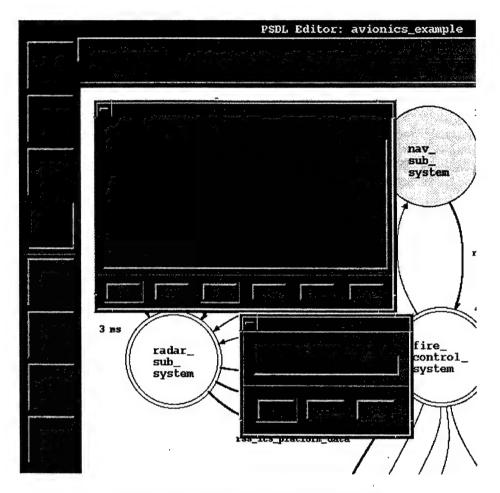

Figure 38. Adding to an Identifier List

As for the data flow diagram, it is visible in the Drawing Window. However, in order to view all attributes of the data flow diagram, the stream and operator popup windows must be accessed. The only method available to view the entire prototype is through the PSDL code generated by the PSDL Editor.

a. Data

A Data indication can be viewed directly from its Data or Display Only component. The user can scroll within the data window through the use of the left and right arrow keys.

b. Data...

The Data... indication is similar to the Data indicator. However, in this case, the data value is typically much larger than the display window. If the data value will not fit within the window, the data value is truncated and a set of epsilons (i.e., "...") is appended. Use the control mechanism to access the entire data value.

$c. \quad Enumeration$

The current Enumeration value is indicated directly on the control component.

d. Label

A Label indication is similar to an Enumeration indication in that any feedback is provided directly on the control component.

$e. \quad Label...$

In this case, much like the Data... indication, a set of epsilons (i.e., "...") is appended to the label to indicate that a data value is associated with the control component. Without the epsilons, a value has not yet been assigned.

f. Hidden

Not all data objects are available in all situations. Some data objects are context depended. For example, a state stream initial value is not relevant unless the stream is a state stream. As a method of enforcing PSDL semantics, several components are displayed based on the context of the operator/stream. The Hides column of Table XIII indicates those components which may be unavailable due to context. Figure 39 depicts the case of a stream which is not a state stream. Here, the State Initial Value Control (Index 51) is "grayed out" and the State Initial Value Display (Index 52) have been removed. In contrast, Figure 34 depicts a state stream in which both of these components are available.

5. Cursor Types

Several different types of cursors are used within the PSDL Editor. The default cursor is the left pointer. It is used for selecting components as described above. Within the Drawing Window, an I-Bar cursor is displayed when the cursor is over

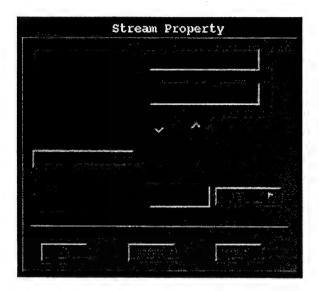

Figure 39. Hidden Components

an object (i.e., data stream or operator). The I-Bar cursor over the data flow diagram is used to indicate to the user that a label can be typed in directly. Finally, a clock face cursor is used to indicate that the PSDL Editor is busy. The clock face cursor is typically encountered when a syntax check or a prototype save function is performed. More will be said regarding the I-Bar cursor in the Data Flow Diagram paragraph below.

6. Mouse Interface

The PSDL Editor requires a two button mouse. The left-mouse button is used to access most functions. The right-mouse button is used to pull up the Stream Property or Operator Property pop-up window, as required. This is accomplished by placing the cursor over the object in question within the DRAWING WINDOW and depressing the right-mouse button. Again, more will be said about mouse interaction in the Data Flow Diagram paragraph below.

Table XIV. PSDL Editor Hot Keys

Function	Menu	Control-key	Diamond-key
Go то Rоот	PSDL	CTRL-R	♦-R
GO TO PARENT	PSDL	CTRL-P	◊-P
DECOMPOSE	PSDL	CTRL-D	\$- D
REFRESH DISPLAY	EDIT	CTRL-F	\$-F

7. Hot Keys

Access to selected menu functions is available through Hot Keys. Those menu items with Hot Keys are identified by an underscore under the Hot Key letter in the pull-down menu (reference Figure 31). Table XIV lists the menu functions, along with the associated key sequence, which are defined Hot Keys.

B. PSDL MAPPING

As was discussed in Chapter III, the PSDL Editor focuses the user on one operator at a time. Figure 40, similar to Figure 21 from Chapter III, indicates the general mapping of the PSDL Editor into the prototype. The PSDL graphical user interface focuses the user on the current operator. There are two exceptions, the TYPES TOOL provides for the specification of abstract data types, at the root level, and the Operator Properties pop-up window supports the functionality of child operators. The background checker provides for the generation of redundant code in order to complete the operator's specification construct.

C. PSDL EDITOR OPERATION

The PSDL Editor is operated through the use of MENU and TOOL BAR functions and pop-up windows. Upon creating a new prototype, the user must start at the root level. Abstract data types may be entered through the TYPES TOOL at any time. However, the specification of the hierarchical tree used to implement the prototype must be performed top-down. That is, the structure of the hierarchical

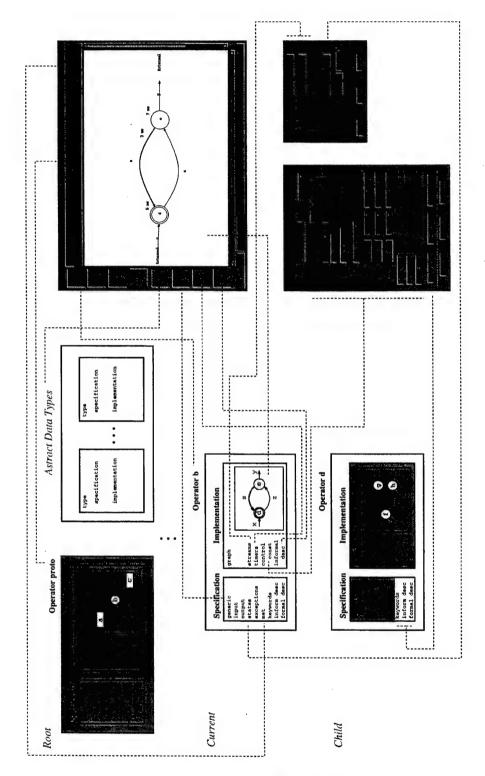

Figure 40. Editor to PSDL Mapping

tree must be specified, starting with the root and proceeding down to the leaves. Development of the prototype in this top-down fashion maintains a syntactically correct prototype. If a bottom-up approach was provided, the prototype would no longer be syntactically correct at each stage of development. The detailed implementation of each operator can be specified in any order.

The network used to implement each PSDL operator is specified within the DRAWING WINDOW, using the tools provided in the TOOL BAR. Implementation details for each composite operator and stream can be entered through pop-up properties windows. Navigation tools are provided to traverse the hierarchical tree. Any time you are using an editor, frequent saves are recommended, which may be accessed through the Menu Bar.

Finally, if help is needed, the PSDL Editor provides help windows, both at the Main Window as well as for pop-up windows. Help is accessed through a text window, as illustrated in Figure 41, with scroll bars available for browsing the message. Press the OK button to exit help.

1. PSDL Editor Segment Synchronization

The PSDL Editor consists of two segments, the background checker and the graph editor, which operate in unison. Each segment performs a portion of the editing task. The background checker is responsible for the input parsing of the PSDL prototype, extracting operators out of the prototype for processing by the graph editor, global syntax and semantic validation, and the generation of PSDL code. The graph editor is responsible for providing a graphical user interface which is used to edit/view the prototype, one operator at a time. The entire prototype is maintained within the background checker. At most one operator can be processed by the graph editor at a time. It is the responsibility of the background checker to accept the operator inputs from the graph editor and to assemble them into a prototype. User directed changes to the prototype are introduced in the graph editor. The background checker automatically resolves the implications of the graph editor produced changes

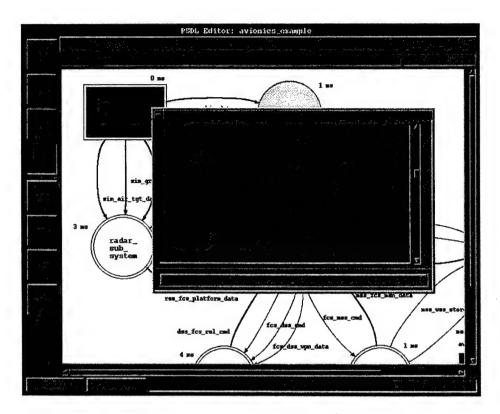

Figure 41. Help Windows

with the prototype. In the event that a discrepancy can not be resolved, an error message is fed back to the user.

The flow of information between the two PSDL Editor segments was depicted in Figure 17 of Chapter III (see page 43). After processing of the prototype, the background checker passes control, along with those objects described in ge_interface.h (reference Appendix D, page 195), to the graph editor. At which point the user is allowed to edit the current operator. All editing of an operator is local to the graph editor. Specific events, requested by the user, result in control being passed back to the background checker. During these events, the background checker synchronizes the prototype with respect to the graph editor. Synchronization is controlled by the ACTION data structure of ge_interface.h. The ACTION data structure also specifies if control is to be returned to the graph editor along with the next operator to be

Table XV. Synchronization Events and Actions

Button/Option	Located on	Action
CHECK SYNTAX button	STATUS BAR	CHECK_SYNTAX
SAVE REQUIRED button	STATUS BAR	SAVE_TO_DISK
SAVE option	FILE MENU	SAVE_TO_DISK
RESTORE FROM SAVE option	FILE MENU	REVERT
EXIT option	FILE MENU	SAVE_TO_DISK or ABANDON
SYNTAX CHECK option	PSDL MENU	CHECK_SYNTAX
Go то Root option	PSDL MENU	UPDATE_TREE
GO TO PARENT option	PSDL MENU	UPDATE_TREE
DECOMPOSE option	PSDL MENU	UPDATE_TREE
ABANDON CHANGES option	EDIT MENU	ABANDON

processed.

The users requested events which result in the synchronization of the background checker and the graph editor are listed in Table XV. Associated with each synchronization event, is an action. Actions are also defined in ge_interface.h.

- •UPDATE_TREE synchronizes the graph editor operator with the prototype maintained by the background checker. No validation is performed.
- •CHECK_SYNTAX synchronizes the graph editor operator with the prototype maintained by the background checker. Syntax and semantic validation is performed.
- •SAVE_TO_DISK synchronizes the graph editor operator with the prototype maintained by the background checker. Syntax and semantic validation is performed. The prototype is saved to a file.
- •REVERT synchronizes the graph editor with the prototype version which resides on disk (i.e., version that was last saved).
- •ABANDON synchronizes the graph editor with the prototype residing in the background checker memory. Only changes made since the last time the prototype was synchronized are abandoned.

2. Data Flow Diagram

The data flow diagram is specified in the DRAWING WINDOW. The PSDL Editor provides a simple drawing package, used to create/maintain the data flow

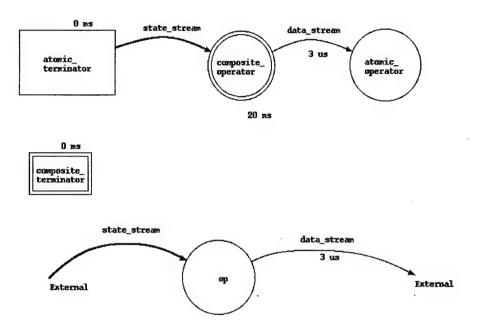

Figure 42. Data Flow Diagram Symbols

diagram. Only a small set of drawing objects are required to represent the data flow diagram. Several variations to objects, such as color and font, are provided to improve the readability of the data flow diagram. These variations have no effect on the operation of the prototype, only on the visual representation of the data flow diagram.

a. Symbols

The data flow diagram consists of a network of operators, connected through streams. Operators and streams are the only objects which are represented in the data flow diagram. Figure 42 depicts all of the symbols which are available to the user.

Chapter II introduced the distinction between operators which are considered to be part of the prototype system and those which reside outside the system. Those operators which reside outside the prototype system partition were specified by assigning a maximum execution time of zero and were called Terminators. Within

the PSDL Editor, Terminators are symbolized by rectangles. All other operators are symbolized by circles. Each PSDL Operator, including Terminators, can be implemented either as a composite operator or as an atomic operator. Atomic operators being implemented using a PSDL supported programming language, composite operators being implemented themselves by a network of PSDL operators. All composite operators are designated by a double boarder in the PSDL Editor, a double rectangle for composite terminators and a double circle for composite operators. In addition to the operator symbol, the data flow diagram is annotated with the operator name and the maximum execution time, as available.

Chapter II also introduced the distinction between streams and state streams. Streams are symbolized by a directed line, state streams by a wider directed line. In both cases, the direction of information flow is indicated by the arrow. Streams and state streams are again annotated with the stream name along with any latency value, as available.

The bottom of Figure 42 depicts the implementation of a composite operator. Streams into and out of a composite operator become external streams within the composite operator's implementation. Such streams are designated with a source or destination of External. Once again, the direction of information flow is indicated by the arrow.

b. Drawing

The data flow diagram is created by selecting a drawing tool from the Tool Bar and positioning the object in the Drawing Window. The drawing tool, once selected, remains selected until another drawing tool is picked by the user. This allows the user to position as many copies of that object in the Drawing Window as desired. Specifically, the following procedures are used create the data flow diagram.

•Operators are added by first depressing and releasing the left-mouse button over the desired Operator/Terminator Tool to select the tool. Then, positioning the cursor over the desired operator/terminator location and depressing and releasing the left-mouse button. Repeat for additional operators/terminators.

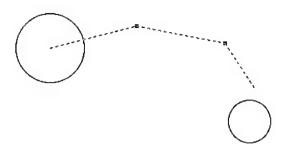

Figure 43. Construction of a Stream

- •Streams are added by first depressing and releasing the left-mouse button over the STREAM TOOL to select the tool. Streams, unlike operators, are created with a sequence of points. At least two points are required to establish a source and destination. Other points can be added to route the stream around other objects on the Drawing Window. The stream source is always the first point selected. The stream destination is always the last point selected. Start the stream by positioning the cursor over the source operator and depressing and releasing the left-mouse button. Streams start and finish at the middle of an operator. There is no need to precisely position the cursor when selecting the source or destination. Route the stream using intermediate points by depressing and releasing the left-mouse button over each location. As the stream is built, it is represented with dashed line segments between anchor points. Anchor points are represented as small black squares, indicating an intermediate point. A stream under construction is depicted in Figure 43. The stream is finalized by positioning the cursor over the destination operator and depressing and releasing the left-mouse button. The resulting stream is a smooth curved line with an arrow at the destination, as depicted in Figure 44. There is no requirement to provide intermediate points within a stream. However, the PSDL Editor does not provide for the addition of intermediate points to a completed stream. Instead, the stream must be deleted and replaced. It is recommended that streams incorporate at least one intermediate point to provide for future routing changes.
- •For composite operators, other than the root operator, inputs and outputs of the composite operator are represented as externals within the data flow diagram. External streams are similar to the streams above, except that they are missing either a source or destination operator. For an external source, position the cursor over the desired "source" location and depress and release the left-mouse button. Continue the stream as discussed above. For an ex-

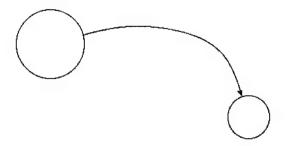

Figure 44. Completed Stream

ternal destination, start the stream as discussed above. In order to complete the stream, position the cursor over the desired "destination" location and double-depress and release the left-mouse button. Care must be taken that the mouse does not move during the double button press. Otherwise, additional intermediate points will be created. The completed external stream is as represented in Figure 42.

- •It the user chooses to abort a stream while in the construction process, the Escape (Esc) can be used to cancel a stream up until completion.
- •Stream and operator labels can be added directly from the Drawing Window. Position the cursor over the object which is to be labeled. Once over the object, the left pointer cursor will be replaced with an I-Bar cursor. At this point, the user can type the label. The label must correspond to a valid identifier for the object. If the cursor is moved during the process of typing the label, the PSDL Editor will assume that you are restarting the label and erase the what has been entered.
- •At any time, depressing and releasing the right-mouse button over an object will access the appropriate pop-up window. After entering the desired data into the pop-up window, depress the OK to accept the data.
- •In order to create a composite operator, the operator must first be selected. This is accomplished by positioning the cursor over the SELECT TOOL and depressing and releasing the left-mouse button. Next, position the cursor over the desired operator and depress and release the left-mouse button to select. The data flow diagram for the composite operator can then be accessed by selecting the DECOMPOSE option from the PSDL MENU.
- •Several of the PSDL Editor functions require the selection of an object. An object is selected through the use of the SELECT TOOL, which is activated by

Figure 45. Selected Operator

depressing and releasing the left-mouse button while the cursor is located over the Select Tool. Objects can then be selected by locating the cursor over the desired object and depressing and releasing the left-mouse button. As an indication that an object has been selected, the anchor points for that object are displayed, as illustrated in Figure 45.

- •In order to deselect an object, depress and release the left-mouse button over any white space in the DRAWING WINDOW.
- •Both operators and streams can be deleted from the data flow diagram. The procedure is the same for both operators and streams. Using the selection procedure described above, select the desired object. The object can then be deleted by the Delete key from the keyboard. If an operator is deleted, then all associated streams will also be deleted. If a stream is deleted, only that stream will be deleted.
- •The PSDL Editor provides the facility to undelete an operator. The undelete operator feature is selected from the EDIT MENU. Selecting this feature access a pop-up window which contains the names of all deleted operators. Undelete the desired operator by locating the cursor over the operator name and double-depress the left-mouse button. This operation can be somewhat confusing in the event that un-named operators are deleted. Such operators show up in the names of deleted operators as a blank lines. However, the same procedure still applies. When an operator is recovered, all associated streams are also recovered. Recovery of deleted operators is available from the time the operator is deleted up until the time that the graph editor passes control back to the background checker. Once control is passed back to the background checker, all deleted operators are purged. If deleted operators are being maintained by the PSDL Editor when control is passed back to the background checker, the user is required to acknowledge that the deleted operators, together with the corresponding portions of the hierarchical tree which resides under the deleted

operators, will be purged. The user can select OK to purge or the user can remain in the graph editor by selecting No or CANCEL.

•The PSDL Editor also provides the facility to abandon all the changes made to the PSDL operator since the last time the operator was synchronized with the prototype. This feature is accessed under the EDIT MENU with the ABANDON CHANGES option.

c. Graph Modifications

Once the data flow diagram has been defined, there are several aspects of the diagram which can be modified to improve the readability of the diagram. These changes have no effect on the performance of the prototype, only on the visual representation of the data flow diagram.

- •Operators can be moved within the Drawing Window. The movement of graphics objects can only be accomplished when the Select Tool is active, as described in the previous section. Using the Select Tool, position the cursor over the desired operator. Depress and hold the left-mouse button. With the left-mouse button held, move the cursor to the desired location and release the left-mouse button. Labels will be moved with respect to the new operator location. Streams paths will be altered as one of the end points is relocated with the operator. None of the intermediate anchor points associated with a stream are moved.
- •Streams paths can also be changed in a similar manner. Select the desired stream, as previously described, to access the stream anchor points. Still using the STREAM TOOL, position the cursor over the desired anchor point and depress and hold the left-mouse button. With the left-mouse button held, move the cursor to the desired location and release the left-mouse button. The location of stream labels will be effected by the new location of the stream mid-point.
- •The size of an operator can likewise be changed through the use of anchor points. Select the desired operator using the SELECT TOOL. Position the cursor over the anchor point, which is in the direction in which you wish to change the operator's size, and depress and hold the left-mouse button. With the left-mouse button held, move the cursor to the desired location and release the left-mouse button.
- •All labels, both names and time values, can be relocated on the DRAWING WINDOW. The label must be selected as previously discussed. Depress and hold the left-mouse button with the cursor over the desired label. Position the

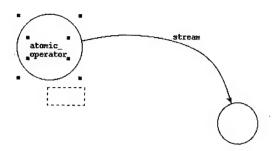

Figure 46. Relocating Operator Label

cursor over the desired location and release the left-mouse button, as depicted in Figure 46.

- •If, in attempting to reposition a stream intermediate point or an operator, one of the associated labels is moved instead, make sure that the label is deselected prior to attempting to move the cursor. This may involve deselecting and reselecting the object.
- •As an aid to increase the readability of the data flow diagram, operators can be colored. Selecting Color from the Edit Menu access a color pop-up window. This function can be utilized in two ways. First, the color of a specific operator can be changed by selecting the desired operator and then assigning a color from the color pop-up window. Second, the color to be used for future operators can be defined by deselecting all operators before accessing the color pop-up window and then selecting a color.
- •Fonts can likewise be changed from the Font option of the Edit Menu. Selecting the Font menu option access a font pop-up window very similar to the color pop-up window. The same two methods of operation for Color apply to Font. First, the font of a specific label can be changed by selecting the label prior to accessing the font pop-up window. Second, the font to be used for future labels can be defined by deselecting all objects before accessing the font pop-up window and then selecting a font. Note that this second mode of operation can not be used to change the font of an existing label by typing over the label with a new font. Instead, the font must be changed using the first method of operation.

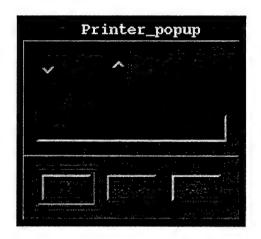

Figure 47. Printer Pop-up Window

d. Printing the Data Flow Diagram

The current data flow diagram can be saved as an output image. This capability is accessed through the PRINT option of the FILE MENU, which presents a printer pop-up window (reference Figure 47). From the printer pop-up window, the image can be saved either to the printer or a file. If file is selected, the user can provide an optional printer name. Only the printer name should be provided in the data window. If no printer name is provided, the image is printed to the standard 1pr printer. The printer must be a PostScript²⁶ printer. If an output file is selected, the data flow diagram is saved to a file using xwd, which produces an X Window System Dump File format. The file name must be provided.

3. Navigation

The graph editor is only capable of displaying/editing the data flow diagram of one PSDL operator at a time. Each prototype consists of a hierarchical tree of PSDL operators. The PSDL Editor provides facilities to traverse the hierarchical tree in order that the entire prototype can be viewed/edited. The mechanism to traverse the prototype is provided within the PSDL MENU. The options DECOMPOSE and GO

²⁶PostScript is a trademark of Adobe Systems Incorporated

TO PARENT are used to traverse up and down the hierarchical tree. Which branch of the tree is traversed, when going "down" the tree, is controlled by the operator which is selected in the data flow diagram. There is only one parent, and thus no option when traveling "up" the tree. A short cut, Go to Root, is provided to directly traverse to the root operator. All navigation menu items are equipped with a hot key to improve efficiency. Hot keys were identified in Table XIV.

4. File Operations

The PSDL Editor provides very simple file operations. Since the PSDL Editor is designed to work within the CAPS environment, there are no provisions for creating a new prototype or saving the current prototype under a different name. The PSDL Editor provides two basic functions, which are located under the FILE MENU: SAVE and RESTORE FROM SAVE. A short cut button, labeled SAVE REQUIRED, is provided on the STATUS BAR. This button is context sensitive to the status of the prototype. If the prototype has not been modified, the button is labeled SAVE NOT REQUIRED. SAVE does just that, saves the prototype to disk. RESTORE FROM SAVE abandons all changes made to the prototype since the last save operation and reverts back to the last saved version. The user will be required to acknowledge that all changes will be lost. Upon completion of the restore operation, the user is returned to the root operator. The save operation will return the user to the original PSDL operator.

The user exits the editor from the FILE MENU using the EXIT option. If required, the user will be prompted to save the prototype. In addition, the user will be informed that all deleted operators will be purged.

Instead of abandoning all changes made to the prototype since the last save command, the user can abandon the changes made to an operator since the last time the operator was synchronized with the prototype. The Abandon Changes option is available under the Edit Menu for this purpose.

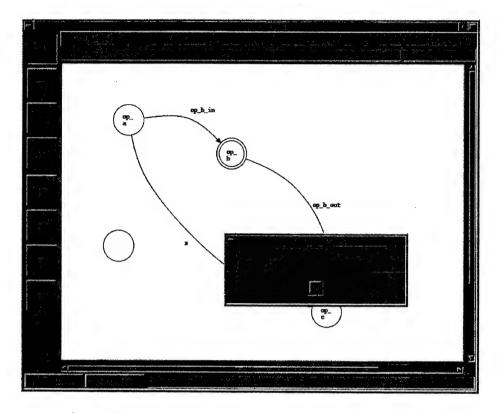

Figure 48. Graph Editor Detected Error

5. Syntax/Semantics Checking

Syntax and semantic validation tests are distributed throughout the PSDL Editor. Most syntax errors and and a few semantic errors are detected by the graph editor. The graph editor performs syntax and semantic validation upon entry of each data object, typically before the data object is written to the editor's internal representation of the prototype. Errors detected by the graph editor are reported with an information pop-up window, which must be acknowledged. An error indication is also provided in the Status Message Window, reference Component 9 in Figure 32, which serves as a reminder after the pop-up window has been acknowledged.

Figure 48 is an example of an error detected by the graph editor. In this example, the operator name op_a is being reused for the new operator in the same data flow diagram. Since op_a has already been used within the composite operator,

Table XVI. Invoking Syntax/Semantic Validation

CHECK SYNTAX button from STATUS BAR SAVE REQUIRED button from STATUS BAR SAVE option from FILE MENU RESTORE FROM SAVE option from FILE MENU SYNTAX CHECK option from PSDL MENU ABANDON CHANGES option from EDIT MENU

an error message is generated. Upon acknowledging the pop-up notice, the Status Message Window will be retained until the next user operation. In this instance, the PSDL Editor automatically removes the duplicate name from the operator, in order to maintain a valid PSDL prototype. Had the error occurred during entry of the operator name from the Operator Property pop-up window, the invalid operator name would not have been removed. Since changes to the operator from the Operator Property pop-up window will not be accepted until all errors have been resolved, the name is retained so that the user can correct the error.

Other validation checks can only be performed from a global perspective. These errors can only be detected by the background checker. While the graph editor performs validation upon data entry, the background checker can only validate the prototype when the prototype is synchronized with the graph editor and the background checker is passed control.

a. Invoking Syntax/Semantic Validation

Syntax and semantic validation by the background checker is performed whenever possible. In order to improve the responsiveness of the PSDL Editor, validation is not performed every time that the editor is synchronized. Table XVI identifies all user action which invokes the background checker to perform validation checks.

b. Error Messages

Upon returning command to the graph editor, any errors detected by the background checker will result in the CHECK SYNTAX button being replaced with the ERROR MSGS button on the Status Bar. By selecting this button, an Error Messages pop-up window will be presented, as depicted in Figure 27. Within the Error Messages pop-up window, the user can select an error message and directly go to one of two operators associated with the error. The Current operator is the operator in which the background checker detected the error. The Parent operator is relative to the operator in which the error was detected.

6. PSDL Output

The output of the PSDL Editor is the PSDL code, which implements the prototype. An example of PSDL code is provided in Appendix B. Identifiers in the PSDL code differ from those observed in the PSDL Editor, with the addition of suffixes in the PSDL code. Hard copies of an operator's data flow diagram can be obtained from the PSDL Editor through the use of the PRINT function under the FILE MENU (reference Figure 31).

V. IMPLEMENTATION

The PSDL Editor has been a team effort. The architecture of having two programs (i.e., the background checker and the graph editor) work together to provide an integrated editor facility immediately lends itself to a team development. Professor Man-Tak Shing was responsible for this version of the background checker. The focus of this research has been the graph editor along with the integration of the two programs. Reference Appendix D for a listing of the complete graph editor source code. The source code for the background checker is not available in this document. However, it is available from the CAPS Research Team at the Naval Postgraduate School, Computer Science department. Appendix E provides guidelines for the installation of the PSDL Editor.

A. ARCHITECTURE OVERVIEW

The PSDL Editor architecture is characterized as having two programs, executed in separate processes, which share information through interprocess channels. The background checker provides the facilities for all file processing, input parsing of a PSDL prototype, syntax and semantic validation of the prototype, and PSDL code generation. The graph editor provides a graphical user interface and facilitates the viewing and editing of the PSDL prototype. Localized syntax and semantic validation is also performed by the graph editor.

1. Program Evolution

The current architecture of the PSDL Editor is the result of an evolution process. The CAPS Release 1 PSDL Editor was the baseline from which this research was initiated. Much of the new design is the creation of Professor Man-Tak Shing, who utilized the PSDL Editor as the class project in re-engineering of a software engineering tool. The results of this class project were then expanded upon to produce this research effort.

a. CAPS Release 1 PSDL Editor

The CAPS Release 1 PSDL Editor was developed by Captain Robert Dixon, USMC [Ref. 13]. Captain Dixon's version of the editor was implemented as two programs, the syntax-directed editor and the graph editor. Data was shared between the two programs using two files. Figure 49 illustrates the architecture used to implement the PSDL Editor. The two files supported the limited data sharing required for the data flow diagram. The first file, gedatatransfile.txt, was used to import the data flow diagram into the graph editor as well as to make intermediate saves. The second file, gedatatransfile2.txt, was used to export the data flow diagram back to the syntax-directed editor. A special file, gedatatransfile.lock, was used to protect the files in case multiple copies of the PSDL Editor were executed in the same directory space.

Within the graph editor, the C++ class GraphObjectList was used to represent the data flow diagram. Captain Dixon's thesis [Ref. 13], describes the class structure used by the graph editor. The data flow diagram itself is represented as a linked list of operator and stream objects. The common features of both of these objects are grouped together in the base class GraphObject, from which the OperatorObject and StreamObject classes are derived. This class structure is depicted inside the graph editor process of Figure 49.

Upon execution of the graph editor, the representation of the data flow diagram was read from gedatatransfile.txt into the GraphObjectList data structure by build_from_disk(). Upon returning to the syntax-directed editor, write_to_disk() was used to write the GraphObjectList data structure into the file gedatatransfile2.txt, to be read by the syntax-directed editor.

A command line argument was used by the syntax-directed editor to indicate if the graph editor was to be executed as a data flow diagram viewer or an editor. The same program was used for both applications.

Most of the code used to facilitate the data flow diagram was used

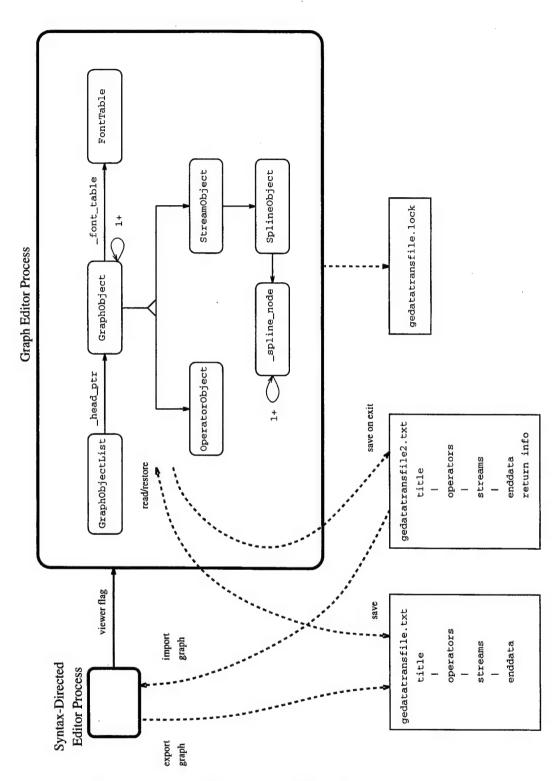

Figure 49. CAPS Release 1 PSDL Editor Architecture

directly to support this research effort. Enhancements were made to provide for the direct entry of operator and stream labels. In addition, an abort was added to the stream creation process. The two files used to share information between the syntax-directed editor and the graph editor were eliminated, along with the associated methods which supported the reading and writing of data to these files. The class structure was maintained. Additional fields and methods were added to the classes in order to support the full specification of a PSDL operator.

b. CS4520 Class Project

Professor Man-Tak Shing introduced the PSDL Editor as the class project for the Naval Postgraduate School course CS4520 (AY96Q4). CS4520 is a topical software engineering class. This particular class dealt with software reengineering. The goal of the class project was to re-engineer the PSDL Editor to provide a more user-friendly editing facility. Only the graph editor was evaluated as part of the class project.

In addition to implementing a new user interface, the new graph editor was to be implemented as a C++ function. All data to be shared between the background checker and the graph editor was to be passed as arguments in the function call. Although only the graph editor was being implemented, the new graph editor was to be integrated with the syntax-directed editor in a single process.

The interface which was used to pass data between the background checker and the graph editor was defined by ge_interface.h. Data structures defined in ge_interface.h expanded upon the data transferred by gedatatransfile.txt, used in the CAPS Release 1 PSDL Editor. Within the graph editor, the original GraphObjectList class structure was maintained. Methods were developed to transfer data between the ge_interface.h data structures and the GraphObjectList class structure. These methods replaced the build_from_disk() and write_to_disk() methods used in CAPS Release 1.

Upon completion of the CS4520 class projects, Professors Valdis Berzins and Man-Tak Shing reviewed all the projects. The project produced by Mr. Douglas

Lange and Mr. Dagohoy Anunciado was chosen to be used for continued research of the CAPS PSDL Editor.

c. Thesis Research

Picking up from the work initiated by Mr. Douglas Lange and Mr. Dagohoy Anunciado, the completion of the graphical user interface was accomplished for the graph editor, along with implementing addition features. Initially, all work on the graph editor was accomplished in a stand-alone fashion, using a simulated background checker driver program. Later, the graph editor was integrated with the background checker. The background checker was created by Professor Man-Tak Shing, using the Synthesizer Generator. The result was an Ada/C program, which was used to call the C++ routine that was the graph editor.

Figure 50 provides a visualization of the PSDL Editor architecture. The PSDL Editor consisted of a single process. The background checker would read the specified PSDL prototype from a file and parse the prototype into the prototype data structure. The current operator would be extracted from the syntax-directed editor data structure and formatted in accordance with the ge_interface.h specification. This data would be passed as arguments to the graph editor function. Inside the graph editor routine, the current operator was loaded from the ge_interface.h data structures into the GraphObjectList class structure (as depicted inside the graph editor process of Figure 49). Upon exiting the graph editor, the process was reversed. The GraphObjectList class structure was dumped into the ge_interface.h data structures, which were dumped into the prototype data structurefor processing.

While development of the graph editor continued, testing was conducted as an integrated unit. X Window System problems were encountered while executing the background checker and the graph editor within a single process. These problems were not observed while executing the graph editor with a simulated background checker driver program.

Additional complications were encountered while troubleshooting the system. With the background checker being implemented in Ada and C and the

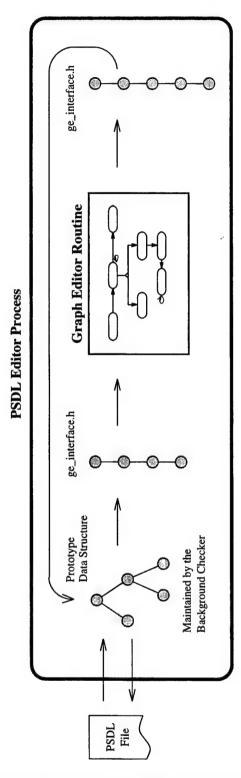

Figure 50. Initial PSDL Editor Architecture

graph editor being implemented in C++, difficulties were encounter using the source debuggers. Finally, errors reported within the X Window System routines could not be traced since there was no source code for the X Window System. This configuration resulted in difficulty troubleshooting all problems with the editor, typically using output statements to debug the program.

These problems were resolved by once again splitting the PSDL Editor into two segments, the background checker and the graph editor, executed in two separate processes. This configuration also supported the source debuggers, which were a great aid to the development of the PSDL Editor.

Figure 51 provides a visualization of the final PSDL Editor architecture, in which the graph editor is executed in a separate process. The background checker is responsible for forking a child process and establishing the pipe lines for interprocess communication. Within the background checker, the graph editor routine has been replaced with calls to transfer the ge_interface.h data structures to the graph editor process. A driver ge_driver.C routine was added to the front of the graph editor. This routine is responsible for accepting the ge_interface.h data structures over the interprocess communication pipe line and passing them onto the graph editor routine. Upon exiting the graph editor routine, the ge_driver.C routine passes the ge_interface.h data structure back to the background checker.

Early testing of the PSDL Editor was accomplished using a small prototype. This prototype was filled with PSDL features, which tested most of the PSDL Editor, however, it was not a very stressful test. Later, additional testing was accomplished using a medium size prototype. Upon testing with the avionics_example prototype, found in Appendix B, problems were encountered. The initial problem, which was obvious to any user, was the delays encountered while using the PSDL Editor. Where one of the initial complaints of the CAPS Release 1 PSDL Editor was the delays between interacting with the syntax-directed editor and the graph editor, the new implementation had even longer delays. Delays from 30 to 45 seconds were

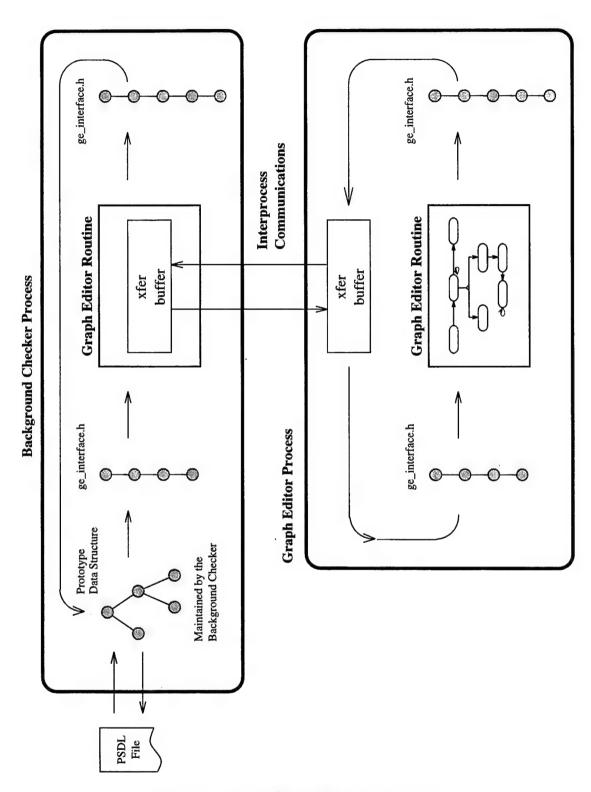

Figure 51. Final PSDL Editor Architecture

typical when navigating through the avionics_example.

Prolonged use of the PSDL Editor resulted in the second big problem, the system ran out of memory. In such a case, the PSDL Editor session had to be aborted. All unsaved changes to the prototype were lost. These problems are further defined under the Lessons Learned paragraph of Appendix B.

Analysis of the PSDL Editor indicated that both the delay and the memory problems were due to the background checker. These problems, as well as the desire to increase portability by removing the reliance on the Synthesizer Generator, resulted in the development of the new Ada background checker.

2. Architecture

The PSDL Editor, in its final configuration, consists of two segments, the background checker and the graph editor. As depicted in Figure 51, each segment is executed within its own process. Communication between the two segments is accomplished using Unix pipes. Two pipes are opened to provide bi-directional communication between the two processes. Input to the PSDL Editor consists of a single file containing the PSDL prototype. Output of the PSDL Editor is also a single PSDL file. All user interaction is performed through the graphical user interface provided by the graph editor. The graphical user interface is implemented as an X Window System application using the Motif widget set. Communication between the two processes is based upon the ge_interface.h data structures.

3. Data Communications

The interface between the background checker and the graph editor supports the bi-directional transfer of PSDL data. In addition, errors detected by the background checker are transfered to the graph editor. While the graph editor commands the background checker to perform the next action. All interprocess communication is defined by the file ge_interface.h. Along with the data structures to support the above communications, ge_interface.h provides common definitions.

a. Graph Description

The structure GRAPH_DESC provides all of the information regarding the prototype required by the graph editor. Only one operator is processed by the graph editor at a time, although some global prototype information is shared. The GRAPH_DESC structure represents the operator's data flow diagram as a linked list of OPERATOR structures as well as a linked list of STREAM structures. The GRAPH_DESC structure is used in bi-directional communication with the background checker and the graph editor.

b. Error Messages

Errors detected by the background checker can only be presented to the user through the graphical user interface provided by the graph editor. The data structure ERROR_MSGS is a linked list of error messages, along with associated operator and parent operator identification. If no errors are detected by the background checker, a NULL pointer shall be provided to the graph editor.

c. Next Action

The data structure ACTION provides the background checker with the commands required to determine the next action to take. Instruction is provided on how to synchronize the data contained within GRAPH_DESC with the prototype data structure, maintained by the background checker. Also provided are instructions on returning to the graph editor with the desired current operator.

1

4. Synchronization

Within the graph editor, all changes to an operator are local to the graph editor. Local changes are synchronized with the prototype maintained by the background checker upon specific user requested events. The synchronization, along with the user specified event, were listed in Table XV of Chapter IV. All synchronization is a function of the background checker. A distinction was made between UPDATE_TREE and CHECK_SYNTAX as a concession to performance. Initially, syntax validation was performed with each synchronization event. However, large delays to perform syn-

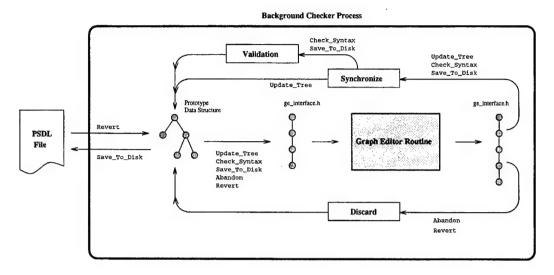

Figure 52. Background Checker Synchronization

tax validation made this option unattractive for all synchronization events. Thus, UPDATE_TREE was added as an option, in which the prototype data structure, maintained by the background checker, were synchronized with any modifications made in the graph editor, but with no syntax validation. This option was provided to improver performance while navigating the prototype. Figure 52 illustrates the type of processing which is expected to be performed by the background checker based on the synchronization command.

B. GRAPH EDITOR DATA STRUCTURES

Within the graph editor, the GraphObjectList class structure is used to maintain all PSDL data. Captain Dixon described this structure in his thesis [Ref. 13]. This class structure has been maintained with this release of the PSDL Editor. A class diagram of the GraphObjectList structure was provided within the graph editor process box of Figure 49.

All information contained within GRAPH_DESC, from ge_interface.h, which does not relate to the data flow diagram was appended to the GraphObjectList

class. Changes were made to all classes that incorporated a time literal. In the CAPS Release 1 PSDL Editor, time literals were encoded as signed integers. All time values in microseconds were encoded as negative times. Values in milliseconds were encoded as positive times. In order to support all time units defined in the CAPS Release 2 PSDL grammar, time literals were maintained with two symbols. One maintained the time value, the other maintained the time units.

Data flow diagram representation information was appended to class objects OperatorObject and StreamObject as applicable. Label and time values, displayed on the data flow diagram, for both operators and streams were modified to function as offsets from the graphics object. Previously, labels and time values were recorded at absolute locations. Methods were added to support the ge_interface.h structures.

C. UTILITIES

Several sets of utilities files were created in the process of developing the PSDL Editor.

1. Graph Editor Utilities

The files ge_utilities.h and ge_utilities.c provide a set of routines for dealing with components of the PSDL Editor. These files were written in C in order to support both the graph editor as well as the original syntax-directed editor (which was written in C due to the Synthesizer Generator). Primarily, the routines in these files support the maintenance of the data structures defined in ge_interface.h. The routine dup_str() is used throughout the PSDL Editor. This routine is used to make a deep copy of a string. In general, the PSDL Editor is implemented using deep copies. Shared values have been avoided.

Another facility provided by the ge_utilities routines is the validation of PSDL constructs. These routines are used by the graph editor to validate identifiers, operator identifiers, type names, keywords, and integer literals.

Table XVII. Inter-Process Communication Routines

readAction()	writeAction()
readErrorMsgs()	<pre>writeErrorMsgs()</pre>
readGraphDesc()	<pre>writeGraphDesc()</pre>

2. Inter-Process Communication

The inter-process communication package was designed to accept the data structures defined by ge_interface.h at one end and recreate the same data structures on the other end. These communication facilities are provided by the routines in the files inter_process_utilities.h and inter_process_utilities.c. Once again, these files were written in C to support both the background checker and the graph editor.

The inter-process communication facility is provided by six routines listed in Table XVII. These routines operate on a xfer_buffer. The xfer_buffer is allowed to expand, doubling in size each time, in order to support the largest data structure. The xfer_buffer itself is sent over Unix pipes in packets with a maximum size of 4096 bytes.

The pipe lines used to facilitate inter-process communications are established by the background checker upon creation of the graph editor process. Two pipe lines are opened, in order to provide bi-directional communication. The two channels to be used are passed to the graph editor as command line arguments. The file ge_driver.C is the main() routine for the graph editor. This file processes the command line arguments containing the channel numbers. The code used to open the pipe lines is provided by the background checker. A sample of code used to facilitate this process may be found in the file sde.c, which is discussed below.

3. Unique Identifier Generator

The incorporation of unique suffixes for operators required a unique suffix generator. The files get_unique_id.h and get_unique_id.c provide this facility.

Once again, these files were developed in C in order to support both the graph editor and the background checker. This implementation uses a file named unique_id.dat from which to generate sequential integers. Future releases of the PSDL Editor shall utilize a data base to provide unique identifiers across a distributed development environment (reference Professor Berzins' memo included as Attachment C). The current implementation is limited to the visibility of the unique_id.data file.

4. Program Development Aids

Several files used develop the PSDL Editor have been included within the source code for the graph editor. While not required for operation of the PSDL Editor, they may be useful for future development efforts.

a. Driver Program

The files sde.c, sde_simulator.h, and sde_simulator.c were developed to perform stand alone testing of the graph editor. The file sde.c provides the main() routine used to fork the graph editor in its own process as well as to establish communications. The sde_simulator files provide a hard-coded prototype which can be edited. Note that this driver program has not been designed to work interactively with the graph editor. The driver program does not contain the facilities to synchronize with the graph editor.

While the source code for the background checker is not contained here, the file sde.c does provide an example of code used to fork the graph editor process and to establish communication pipe lines.

b. Debug Routines

In the process of integrating the background checker and the graph editor, often there was a need to examine the data contained within the ge_interface.h data structures. A collection of routines provided in files ge_utilities_debug.h, ge_utilities_debug.c, and ge_interface_labels.h were developed to display and print to a file the contents of the ge_interface.h data structures.

D. GRAPH EDITOR

The files used to implement the graph editor, roughly organized by function, are listed in Table XVIII. The graph editor routine which actually edits the prototype is edit_graph(), defined in graph_editor.C. This routine is called from ge_driver.C upon receiving the ge_interface.h data structure from the background checker. At every synchronization event, this routine is exited. Within edit_graph(), the Motif windows are initialized. Initialization is performed once, based on the symbol motif_initialized. After the initial entry, the Motif environment is assumed to exist. Motif data is maintained within global objects in order to provide persistence.

Typically, a Motif application expects to pass control over to Motif until the program terminates. In order to support the PSDL Editor, the Motif control loop had to be maintained within the graph editor. The edit_graph() routine enters a loop which dispatches X Window System events until a synchronization event is selected by the user to exit the graph editor.

Table XVIII. Graph Editor Source Code Files

Function	Header File	Code File

VI. CONCLUSIONS AND RECOMMENDATIONS

Overall, this research was successful in the development of an improved PSDL Editor facility. While full graphical user interface support was not provided for all features of PSDL, sufficient portions of the language were supported to demonstrate the concepts of the improved interface.

Since the aspects of the PSDL Editor addressed by this research primarily relate to human factors, any validation of the improvements made would have to be accomplished with a survey of users. Such a survey was not conducted as part of this research, so no conclusions can be stated regarding the effectiveness of the improvements. However, a few personal observations from experience obtained while testing the PSDL Editor can be made along with some recommendations for future research.

A. RESULTS OF RESEARCH

Based on personal experience with the PSDL Editor, I would submit that the artificial boundary between the syntax-directed editor and the graph editor has been significantly reduced. What remains of the boundary is the batch mode of operation when it comes to global syntax and semantic validation as well as any delays encountered switching between the two programs. While early versions of the improved PSDL Editor had significant delays, optimizations within the background checker have resulted in acceptable delay times, even for large prototypes.

Use of pop-up windows to specify the details of an operator or stream has streamlined the development of prototypes. Immediate access to complete details of a data flow diagram object are now one button away. No longer are users compelled to complete the data flow diagram prior to entering any of the details, due to the long delays and steps required to access this data. Direct entry of operator and stream

labels has been a significant step in streamlining the development process.

Previous problems encountered by users attempting to locate a construct within the syntax-directed editor should not be as prevalent with the use of pop-up windows. These problems, associated with a linear translation of the PSDL grammar, are reduced by the depiction of all options within the pop-up window. Options displayed in the pop-up window are consistent with the current configuration of the object. No longer must a user remember the ordering of PSDL constructs, they are visible to the user from the pop-up window. Ghosting of an option acts to remind the user of the availability of an option while the physical location of the options suggest dependencies between options.

An improvement which should reduce the amount of lost work in the PSDL Editor was the simplification of file operations. All file save operations now write directly to the prototype file. There is no longer an intermediate file to which the editor saves the prototype, from which users have lost entire edit sessions due to a misunderstanding of the save procedure. The currently implemented file system should be intuitive to most users of personnel computer software.

As previously mentioned, not all features of PSDL were implemented with the graphical user interface. Several features of PSDL were determined to be too complex for this initial implementation of the graphical user interface. These features included abstract data types, constraint options, expressions, and the specification interface. Although not supported by the graphical user interface, these features were not left unsupported. Text windows were provided within the graph editor for the specification of these constructs using PSDL. Being some of the more complex PSDL constructs, they are also some of the more advanced features. And while all these features are critical to the use of PSDL, they are most often used by more advanced users. The result is that the PSDL Editor provides sufficient capabilities to be utilized for prototype development by the average user. More advanced users can still utilize the PSDL Editor, however, they will require more knowledge of PSDL to access these

B. CRITIC OF RESEARCH

As with any program, criticism can be made of the design and implementation. This program offers no exception. Discussed below are observations of problems in the design and implementation. I do not point a finger to any previous author of the PSDL Editor for problems with this release. All of the problems, both in design and implementation, were mine to address. What few problems were inherited from previous authors were most likely small problems which I have amplified in "improving" the program. But just as there was insufficient time to support all features of PSDL, there was insufficient time to address these "features" of the PSDL Editor.

1. User Interface

The mapping between the PSDL Editor's graphical user interface and PSDL is not clean. For instance, the functionality of an operator's specification is accessed through the pop-up window for a composite operator. This mapping does not support the root operator.

The drawing operation of the data flow diagram is too slow. While there may be a tendency to coerce the user to maintain good programming practices and keep the data flow diagram simple, it should not be accomplished by aggravating the user with delays. The drawing of streams, and especially state streams, is extremely slow. The system is not usable, when executed remotely over phone lines.

Associated with the delays involved with drawing the data flow diagram, the data flow diagram is too sensitive to change. Unintentional changes are typically made to the data flow diagram as the user attempts to navigate the prototype. In order to navigate through the prototype, the user must select an operator. If the user moves the mouse while the left-mouse button is depressed, the object will be moved and the user will have to wait for the data flow diagram drawing to be updated.

The pop-up facilities to modify an operator's color or a label's font as well as those used to recover a deleted operator are rudimentary. No provisions are made to indicate the currently selected color or font. No provisions are made to Ok the selection or to cancel the operation. The user is required to know how to select the item with a double mouse action as well as the current value, in case the user wishes to leave the value unchanged. No feedback is provided to the user to indicate that a color or font change is being performed on a specific object or the default value is being changed. The restoration of an unlabeled operator is a guessing game for the user.

2. Implementation

The PSDL Editor started out as two programs, executed in separate processes. As an update to the design, it was converted over to a single program, executed in a single process. Problems encountered with this configuration forced it to be split once more into two programs, executed in separate processes. Again, problems were encountered which forced a change to the design of the editor. This last change has seen the removal of the Synthesizer Generator produced background checker, to be replaced with an Ada version. With this latest change, no modification was made to the interface between the background checker and the graph editor. With the design changes which have occurred so far, maintaining two separate programs may be wise. However, at this point, two separate processes appears to be unnecessary. Associated with two separate processes is a lot of communication overhead which could be removed, thus simplifying the program. Combining the two tasks into one procedure would also improve the performance with respect to delays, thus further reducing the artificial boundary between the background checker and the graph editor.

With the evolution of the graph editor, the program has become "messy". The program has appeared to have lost any structure as new features are simply added. Global objects are used throughout the program to provide communication with the graphical user interface. Files have become much too large. The graph_editor.C

file, once printed, goes on for fifty pages. The draw routine alone is ten pages long, with far too many levels of indentation. Even simple maintenance to the program becomes complex and error prone with this absence of organization.

Within the graph editor, a clean representation of data objects has not been maintained. Redundant data is maintained throughout the data objects. For instance, which graphical object is selected is indicated within the data structure for that object. Thus a house keeping process must be maintained to ensure that only one object is selected at at time, clearing all other selected objects. The result is that, occasionally, multiple graphic objects appear to be selected. The user is confused at this point. Only by selecting and de-selecting each object that appears to be selected can the indications be cleared up.

C. RECOMMENDATIONS FOR FUTURE RESEARCH

In the process of re-engineering the PSDL Editor, many additional ideas come to mind. Most of which are much too late to be incorporated into the design of the system. The following is a collection of ideas which should be used to stimulate thought for the next release of the PSDL Editor.

The current design of the graphical user interface provides a very limited view of the context of an operator. The user is presented with the data flow diagram of the operator, but no visualization of the context of the operator. The CAPS Release 1 PSDL Editor provided some indication of external streams. Even this limited view of context was removed from this release of the PSDL Editor. Future releases of the PSDL Editor should prompt the user with options available from the operator's context. Figures 53 and 54 depict an initial attempt to provide the user with such a context with respect to streams. Figure 53 illustrates the user's options of entering a stream name directly into the data entry window or to select from a list of predefined streams. Figure 54 depicts all streams which are currently defined in the context, along with an indication of external streams and their use, state streams and their

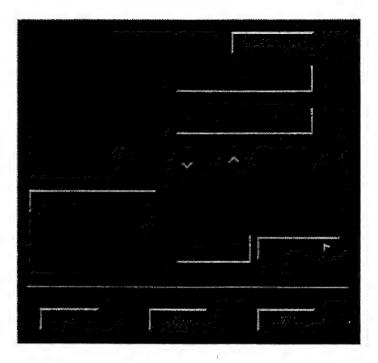

Figure 53. Stream Property Pop-up with Predefined Option

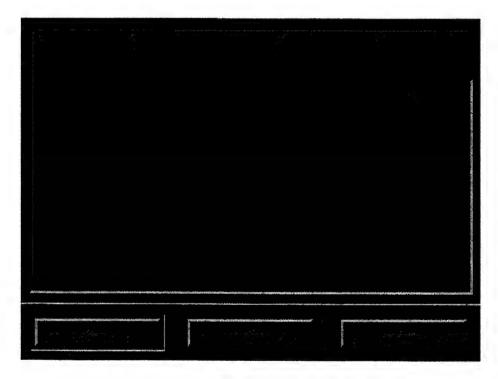

Figure 54. Stream Predefined Context

initial value, and the stream type. Due to scheduling constraints, this option was never incorporated into the final release of the PSDL Editor.

Options available for improved data flow diagram editing capabilities mostly involve modifications to streams. Such features as being able to remove or add intermediate stream anchor points as well as being able to change the direction of a stream would improve the user's ability to modify an existing data flow diagram. Higher level edit features for working with operators would also greatly improve the user's ability to modify a prototype. Such features would include the ability to select a group of operators from a single data flow diagram and form a composite operator from them, thus adding one more level to the hierarchical tree. The reverse operation could also be provided as a feature, to remove a level from the hierarchical tree. Copy, cut, and paste operations on selected operators could be provided. Modifications to object properties, such as color and font, could be performed on several selected objects simultaneously.

Improved semantic validation capabilities could be incorporated. Possible candidates include detecting cycles in data flow diagrams which are not broken by state streams and global validation of timing constraints. This release of the PSDL Editor took a step backward in editing an existing prototype. In order to edit a prototype, the editor must be able to parse the input file. Syntactical errors in the input file could result in the PSDL Editor not being able to parse the prototype. Previously, the PSDL Editor would at least allow the user to edit the prototype text if a syntactical error was detected. With this release, the PSDL Editor is not usable on a corrupted prototype.

While the CAPS environment provides access to the complete set of CAPS tools, many of these tools could be integrated with the PSDL Editor. Tighter integration of CAPS tools could provide:

• Automatic generation of skeleton files to support atomic operators. This capability has become a necessity with the inclusion of unique suffixes to operators.

- •Direct access to an editor to view/edit an atomic operator implementation.
- •Access to the reuse library from the PSDL Edit based on an operator's specification.
- •A PSDL Editor mode for performing maintenance on the reuse library.
- •The ability to save a prototype as a new revision within the Evolution Control System.
- •The ability to merge prototypes.
- •The ability to examine the prototype schedule from the editor. Computer assistance should be provided on how to modify the prototype in order to change the schedule.

Finally, with the advances made in internet and intranet technologies comes the opportunity to improve upon existing applications. The migration of the PSDL Editor's help facilities to a hyper-text mark-up language (HTML) based system should be straight forward. Such a system would be a great improvement over the existing capability. The conversion of the PSDL Editor over to a internet/intranet application would be much more involved. However, the resulting facility would provide a portable editor capable of supporting distributed prototype development.

APPENDIX A. PSDL GRAMMAR.

The following is the complete specification of the Prototype System Description Language (PSDL) syntax in an extension of Backus-Naur Form (BNF) [Ref. 14].

The BNF description of PSDL specifies the sequence of symbols which constitute a valid PSDL prototype. BNF describes the language in terms of production rules. Each production rule equates a non-terminal symbol to a sequence of terminal and non-terminal symbols. Terminal symbols are symbols which can occur in PSDL. Non-terminal symbols are metalinguistic variables whose value is a sequence of symbols which represents a PSDL construct.

Terminals are represented as **bold** symbols (e.g., **operator**). Non-terminals are enclosed in angle brackets, \langle and \rangle (e.g., $\langle psdl \rangle$). Additional metasymbols are introduced in the extension of BNF to reduce the number of productions and non-terminals. These metasymbols are defined as:

- •Square brackets, [], enclose optional items.
- ulletCurly braces, $\{\ \}$, enclose items which may appear zero or more times.
- •Vertical bars, |, represent a choice between items.
- •Parentheses, (), represent a grouping of items.

In some cases, the metasymbols used are also used as terminals within PSDL. In order to avoid confusion, such terminal symbols are enclosed within single quotes, (e.g., ')').

For ease of reference, each production rule is numbered on the left hand side. These numbers are not part of the PSDL syntax.

APPENDIX B. PROTOTYPE EXAMPLE

Early in the development of the PSDL Editor, a small prototype created by Dr. Shing was used for testing purposes. This prototype consisted of a few operators, and hence did not present a sufficient test case for the PSDL Editor. The lack of size of Dr. Shing's prototype lead to the creation of an avionics_example prototype.

The goal of the avionics_example prototype was to use as many features of PSDL as possible and provide a medium to large size prototype to test the PSDL Editor. Since the PSDL Editor has limited facilities for types and generics, examples of these features were limited or non-existent. In addition, no attempt was made to test all combinations of expression evaluations.

In addition, no attempt was made to provide a full avionics suite. The example presented is not intended to reflect an actual avionics suite, although aspects of the prototype can be found in aircraft that are currently in the United States Air Force inventory.

1. ARCHITECTURE

Figure 55 represents the avionic suite that is modeled in the prototype. The avionic suite consists of a six subsystems: Fire Control System (FCS), Radar Sub-System (RSS), Navigation SubSystem (NSS), Weapon SubSystem (WSS), Display SubSystem (DSS), and the Mass-Storage Subsystem (MSS). The FCS contains two dual-redundant processors, FCS_1 and FCS_2. The RSS contains both a radar antenna and an inertial platform on the antenna, which can be used as a backup navigation source. Two bomb racks are provided in the WSS.

The avionic suite contains two data buses. One is used for the RSS and NSS. The other is used for the WSS, DSS and MSS. A single bus controller is used to coordinate all messages traveling over the buses. The FCS performs all bus controller activities. Since the FCS is dual-redundant, one FCS processor is designated as the

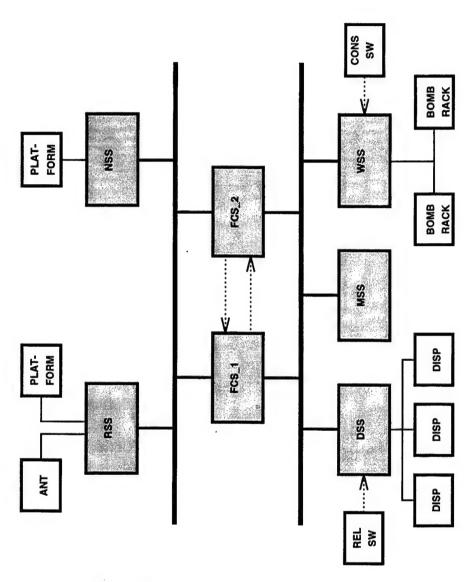

Figure 55. avionics_example Architecture

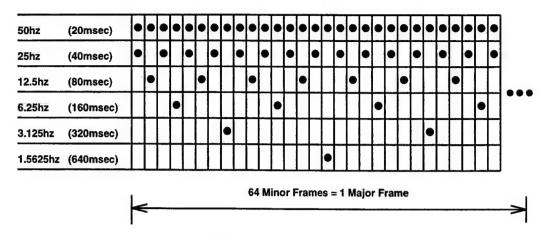

Figure 56. Minor Cycle Task Scheduling

bus controller while the other monitors the health of the bus controller. If the bus controller should fail, the second FCS processor takes over bus controller activities.

All tasks performed by the avionic suite are scheduled to be accomplished at different rates. The execution of each processor is divided into minor cycles and major cycles. For a typical avionic suite, the processors are executed at 50Hz. Thus, each minor cycle lasts for 20 milliseconds. A major cycle would consist of 64 minor cycles. All tasks are expected to be accomplished in a major cycle. During a minor cycle, tasks from two rate groups are performed. This is depicted in Figure 56 where each column represents a minor cycle. During each minor cycle, tasks from the 50Hz rate group and a slower rate group are performed.

2. MAPPING TO PSDL

Just as the design of an avionic suite would start with a high level diagram and decompose each component of the design, the prototype consists of a root operator, avionics_example, which is composed of a PSDL operator for each subsystem. In the case of the NSS, a simple pass-thru model will be used. No additional decomposition is required for a simple operator. Thus, the NSS is implemented in Ada. The other subsystems are more complex, and thus, are decomposed into a PSDL graph

implementation.

Although no software base is provided for this prototype to facilitate the execution of the prototype, two additional prototype components are required to complete the model. An environment_simulation operator is required to simulate the aircraft motion as well as the target environment and an air_vehicle_interface operator is required to facilitate the displays produced by the display_sub_system as well as providing a user interface for switch actions. Both of these operators are external to the avionic suite and are thus represented as terminators (square boxes) so that the execution time is not counted against the avionic suite.

For the purposes of this prototype, the timing model previously discussed is too complex. Instead, tasks will be accomplished at either 50Hz, 25Hz or 1Hz. Each subsystem that performs tasks at different rates contains a mode control operator which schedules the tasks.

In the actual avionic suite, each processor executes in parallel. Tasks within a processor are performed serially. While PSDL does not preclude the parallel execution of operators, CAPS Release 1 was implemented on a single processor. This prototype is also designed to be executed on a single processor. In order to maintain the desired execution rate of 50Hz, each subsystem is assigned an execution time which is a fraction of a minor cycle (reference Figure 57). Since the processing of each subsystem is simulated, the calculations performed can be greatly simplified in order meet the timing requirements.

3. PROTOTYPE

The decomposition of each PSDL operator for the avionics_example prototype is provided in Figures 58 through 64.

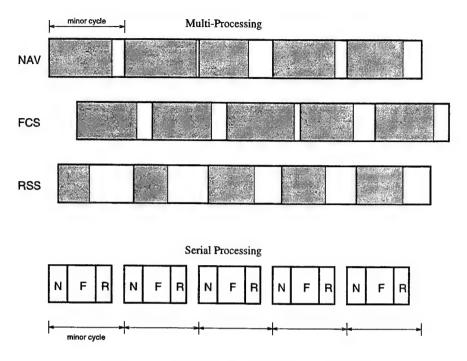

Figure 57. Serializing Multiple Processors

4. CAPS RELEASE 1 COMPATIBILITY

Although this implementation of the PSDL Editor incorporated changes to the CAPS Release 1 grammar, an attempt was made to schedule the prototype using CAPS Release 1^{27} . Before the prototype can be scheduled, a successful translation must be accomplished. It was found that the translator would not accept the **property** construct added to the PSDL grammar. Nor did the translator accept an implementation language other than Ada^{28} . The inclusion of operator and vertex identification numbers to the $\langle op_name \rangle$ also caused compatibility problems. Since the $\langle op_name \rangle$ provided in an $\langle operator \rangle$ $\langle component \rangle$ does not include the vertex identification number, where the $\langle op_id \rangle$'s used in the $\langle data_flow_diagram \rangle$ does,

²⁷Note that there is no implied compatibility of this implementation of the PSDL Editor with CAPS Release 1. This experiment was intended to identify compatibility issues.

²⁸The CAPS Release 1 PSDL Editor did not accept a mixed case Ada. An all upper case ADA was accepted. Additional problems encountered with the CAPS Release 1 PSDL Editor include the finish within construct and Missing_Info containing two underscores in succession

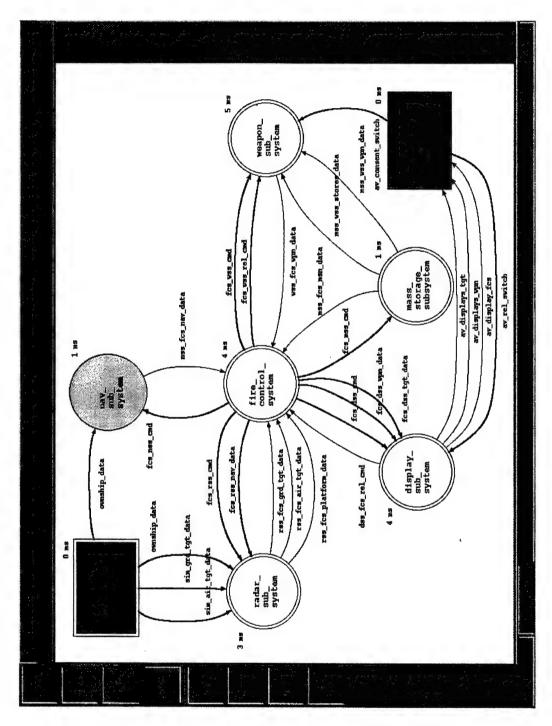

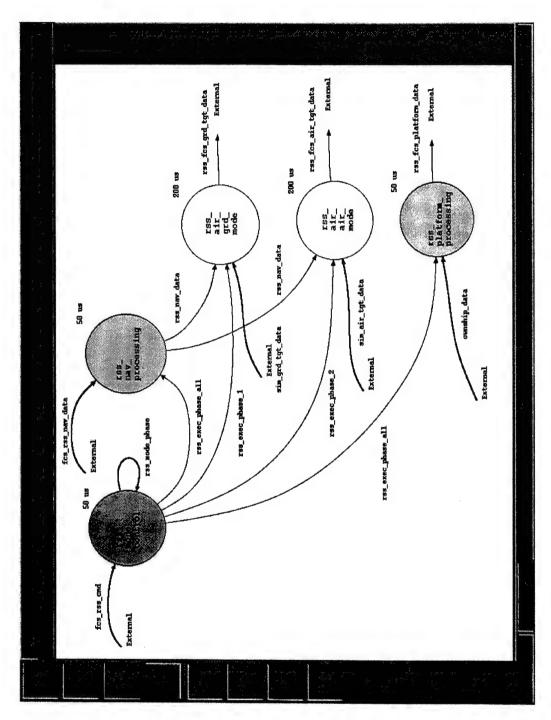

Figure 58. avionics_example Root Operator

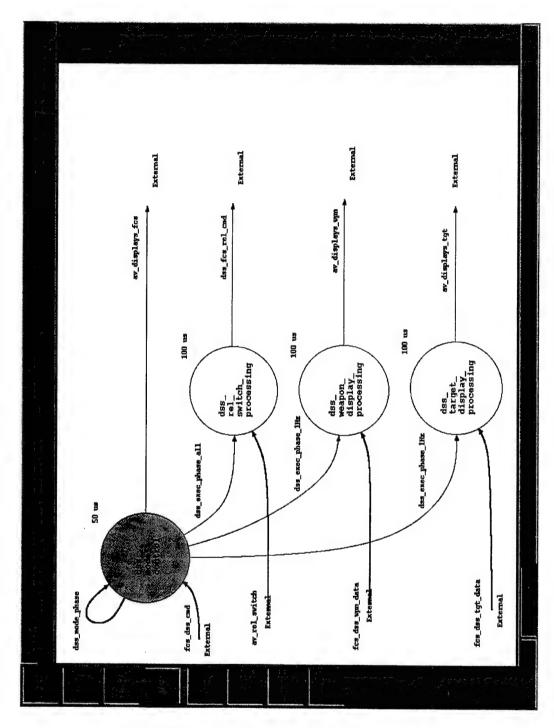

Figure 60. avionics_example DSS Operator

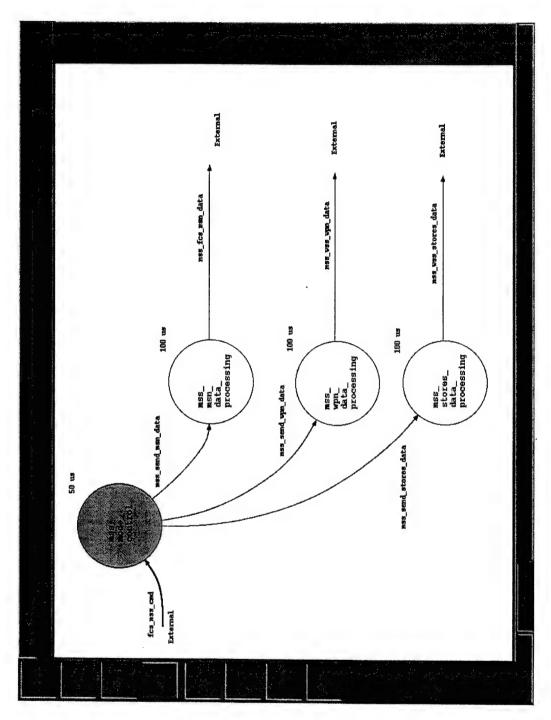

Figure 61. avionics_example MSS Operator

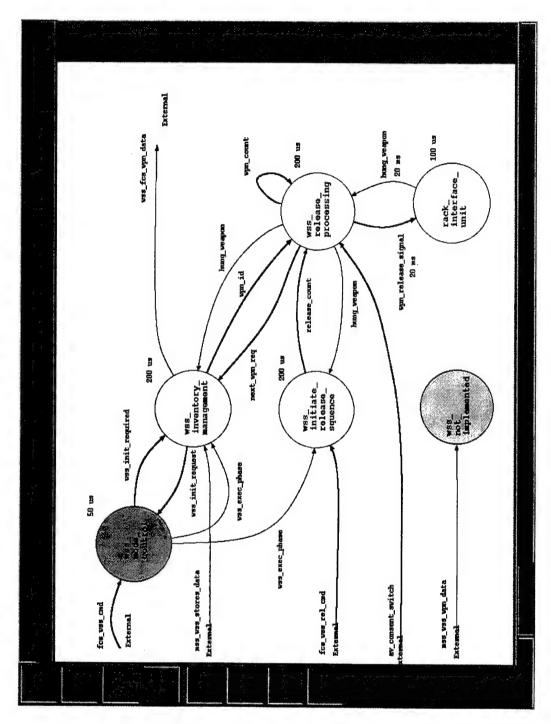

Figure 62. avionics_example WSS Operator

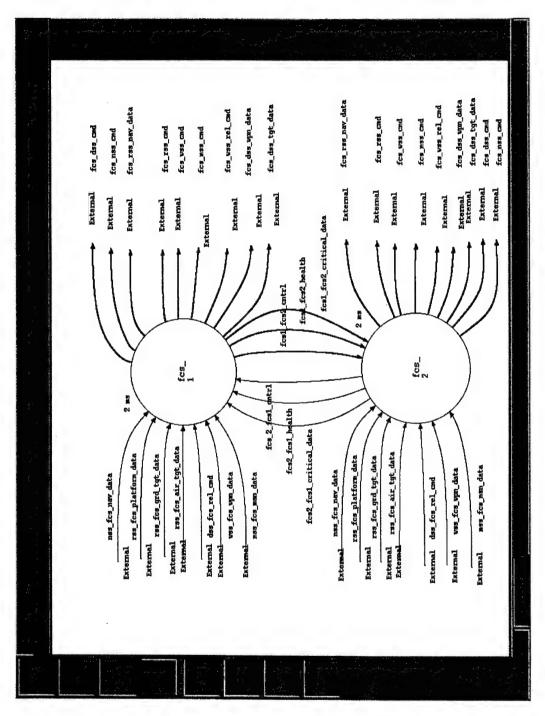

Figure 63. avionics_example FCS Operator

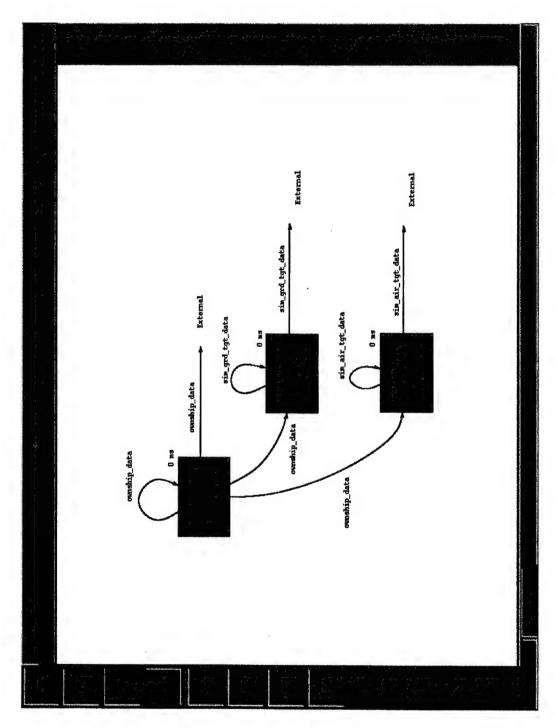

Figure 64. avionics_example Environment Operator

each of these $\langle operator \rangle$ $\langle component \rangle$'s are reported as multiple root operators.

After using a text editor to correct these problems, no additional errors were reported by the translator. However, this does not imply that there are no other compatibility issues. Only that no other errors were detected. At this point, the prototype was scheduled. Only one additional error was detected by the scheduler. The scheduler raised a TIME_INFO_ERROR exception for having a zero MET and a non-zero PERIOD.

No additional testing was performed beyond obtaining a valid schedule. However, additional compatibility issues probably still exist but not reported. The lack of operator and stream identification numbers within $\langle control_constrains \rangle$ will most likely cause additional problems.

5. LESSONS LEARNED

The early use of the avionics_example prototype in the development of the PSDL Editor was extremely beneficial. Problems were detected with the PSDL Editor that required major rework of the system while there was still time in the schedule to accommodate changes. Specifically, it was found that the PSDL Editor required a large amount of time to perform syntax checks and took an enormous amount of system memory. In addition, the protocol used to exchange information between the background checker and the graph editor failed for large prototypes. Neither of these problems were readily apparent from the use of smaller test cases.

In stepping from a small prototype to a large prototype, it was apparent that the PSDL Editor required too much time to traverse the prototype. It was typical to take 45 seconds to move from one level of the prototype to another. Timing analysis indicated that the largest component of this delay was due to updating the attribute tree maintained by the background checker, which uses Synthesizer Generator routines to maintain the attribute tree as in CAPS Release 1. However, each of these routines also updated the syntax-directed editor window, which resulted in even longer delays.

The syntax-directed editor window is not used in this version of the PSDL Editor, and thus resulted in wasted processor time. System performance was improved through the redesign of the background checker. A new Ada/C background checker, which did not use the Synthesizer Generator code, is now used to maintain the prototype data structure. This redesign resulted in greatly improved performance during the traversal of the prototype and significant improvements in the delays encountered during syntax checks and save operations.

In the process of working with the avionics_example, it was found that the syntax-directed editor reported being out of memory (virtual memory swap space). The problem appeared to be one of accumulation. The syntax-directed editor started with a reasonably sized workspace. However, as the user traversed the prototype, the memory requirements grew until the available swap space was no longer able to accommodate the program. This problem is now solved with the new background checker.

Between the background checker process and the graph editor process, two pipes are used to provide bidirectional communication. The protocol used to communicate worked fine for small prototypes. However, when the avionics_example prototype was used, this protocol fell apart. The error resulted from the maximum limit on the size of read and write operations on the pipe. Using the larger prototype, this limit was exceeded. A solution was obtained by transmitting the buffer used for inter-process communication using multiple packets of a maximum size reflective of the pipe limitations.

Besides these errors, modifications to the user interface were identified to improve user interaction. Once again, these modifications were identified after repeated use of the editor. They were not readily apparent from the entry of one or two operators.

X is positive East, Y is positive North, Z is positive Up. Heading will be measured from the X axis, positive Counter-Clockwise. }
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              operate the avionics prototype. Since the operations performed
by this operator do not correspond to processing performed, but
instead are a simulation of a physical process, the execution
dynamic motion will be simulated, the course taken by the air vehicle will be static. This model provides for a constant flight heading, velocity, and altitude. No accelerations,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       simulation, earth_model, ground_target_model, air_target_model,

Subject: explanation of the new unique suffix conventions

Status: RO

Unique integer suffixes in CAPS Release 2

Valdis Berzins, 7/25/96

To properly implement PSDL scope rules, which say that the names of the children of a composite bubble are local to that bubble, we need unique internal names for PSDL operators. To allow multiple instances of the same type operation, we also need unique internal names for graph nodes.

The implementation in CAPS Release 2 will be based on the following conventions:

1. The psdl editor will supply unique internal integer suffixes for the names of stand-alone PSDL operators.

These suffixes WILL NOT BE VISIBLE TO THE USER OF THE EDITOR, and will be supplied automatically in generated skeleton code for operators with IMPLEMENTATION ADA.

The purpose of these suffixes is to allow two different composite bubbles to have children of the same name without conflicts between the Ada module names.

- 2. Names of PSDL data types will not have automatically created integer suffixes, because they are not needed.
- 3. Names of operations of PSDL data types will not have automatically created integer suffixes. This implies the translator does not have to resolve overloaded operators.
- 4. The psdl editor will add a unique integer suffix to each operation name to get the name of the corresponding graph node. This enables multiple instances of an operation of a data type to consistently co-exist in the same graph.
- 5. In release 2 the integer suffixes will be unique throughout the entire prototype and will be obtained from a procedure local to the editors (because there will be no DDB in release 2). In future releases the suffixes will be unique across all prototypes developed at a given installation, and will be obtained from a unique id server in the DDB.

Some consequences of these conventions:

- A. The name of the ada operation can be recovered from the name of the graph node by removing a trailing numeric suffix of the form ("_" digit+). Note that the name of the graph node does not include the optional parameter binding part.
- B. For prototypes created under caps release 2, graph nodes corresponding to stand-alone operators will have two integer suffixes, but only the second one need be recognized by computations in translation. The schedulers are only concerned with graph node ids, and hence are not affected by this convention.
- C. Graph nodes corresponding to operations of a PSDL data type have a single suffix. This suffix enables multiple instances of a type operation to appear in a graph without danger of confusion.
- D. Attributes and control constraints are located by visual navigation through the graphic editor, to avoid confusing the correspondence between graph nodes and control constraints.

E. PSDL files created under release 1 may not have these suffixes. The concrete parsing rules of the sde should recognize such cases, and should add the needed suffixes if they are missing, to enable the sde to read old psdl files (CAPS release 1 format). **EXAMPLE** Displayed form of the psdl, with explanatory comments: OPERATOR o -- internal name o_13, graph node o_13_20 SPECIFICATION INPUT a: boolean OUTPUT b: integer **END** IMPLEMENTATION ADA END TYPE t -- internal name t OPERATOR o -- overloaded, internal name o, graph node t.o_21(b|) SPECIFICATION INPUT x: integer END OPERATOR o -- overloaded, internal name o, graph node t.o_22(|a) SPECIFICATION OUTPUT y: boolean END END IMPLEMENTATION ADA END OPERATOR top SPECIFICATION END **IMPLEMENTATION** GRAPH -- internal form of the graph, whose display is suppressed: VERTEX o_13_20 VERTEX t.o_21(b|) VERTEX t.o_22(|a)

EDGE a $t.o_22(|a) \rightarrow o_13_20$ EDGE b $o_13_20 \rightarrow t.o_21(b|)$

END

Displayed form of the graph:

1		-	a	1	1	b	1		- 1
1	t.o(a)	- 1	>	1	0		->	t.o(b)	- 1
		-		1	1		- 1		1

APPENDIX D. GRAPH EDITOR PROGRAM SOURCE CODE

The following is the complete source code listing of the graph editor portion of the PSDL Editor. The original graph editor source code was developed by Captain Robert Dixon, USMC [Ref. 13]. Additional work was performed by Mr. Douglas Lange and Mr. Dagohoy Anunciado as part of the NPS CS4520 (AY96Q4) class project. In several of the graph editor files, the authors of the graph editor have adapted code written by others. Such instances are credited within the source files.

For a starting point, ge_driver.C contains the main() routine for the graph editor. This routine is called by the syntax-directed editor to start the graph editor. After initialization and establishing communications with the syntax-directed editor, the routine edit_graph() is called, which can be found at the end of the file graph_editor.C.
